## Acknowledgments

Firstly, I'm proud to express most of the acknowledgments to my dear parents for so much education, and my brother, Pedro, and Maite for their unconditional support.

I'm profoundly grateful to Dr. Márcio Weber Paixão, for giving me this opportunity and spending his time teaching me. His passion and skill for chemistry are, without a doubt, the best I have ever seen. Besides providing an exciting educational work environment, he has shown true concern and extraordinary lab experience for which I will always be incredibly grateful.

I would like to thank all the professors of the Chemistry Department at the Federal University of São Carlos (UFSCar) for the wonderful class and seminaries. Also, thank my friends in and outside of the lab of LSPN during the years 2016-2018.

Also, to the agencies CNPq, FAPESP, and CerSusChem for the financial support of the project.
"This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001."

## Resumo

## SÍNTESE COMBINATORIA MULTICOMPONENTE DE CATALISADORES PROLIL PEPTÍDEO-LIPOPEPTÓIDES HÌBRIDOS: APLICAÇÃO NA ADIÇÃO DE MICHAEL ASSIMÉTRICA EM MEIO AQUOSO

Este estudo descreve a síntese de uma nova biblioteca de catalisadores híbridos de peptídeos prolil-lipopeptóides através de uma abordagem combinatória multicomponente. Para o projeto deste catalisador, levamos em consideração o crescente interesse no desenvolvimento de tecnologias mais sustentáveis e a recente contribuição de nosso grupo de pesquisa nessa área. Para este fim, usando o protocolo de Ugi-quatro componentes, incorporamos cadeias laterais lipídicas na arquitetura do catalisador híbrido peptídeo prolil-peptóide. A inserção de funcionalidades com propriedades anfifílicas fornece propriedades surfactante ao organocatalisador. Os compostos foram ainda avaliados como organocatalisadores na adição ambientalmente amigável de aldeídos a nitrostirenos. Os adutos de Michael foram obtidos em altos rendimentos, diastereosseletividades e excelentes enantiosseletividades utilizando baixa carga de catalisador, empregando água como solvente sem a adição de outro aditivo.

#### Abstract

MULTICOMPONENT COMBINATORIAL SYNTHESIS OF PROLYL PEPTIDELIPOPEPTOID HYBRID CATALYST: APPLICATION IN THE ASYMMETRIC MICHAEL ADDITION UNDER AQUEOUS ENVIRONMENTAL

This study describes the synthesis of a new library of prolyl peptides-lipopeptoid hybrids catalysts through a multicomponent combinatorial approach. For the design of this catalyst library, we took into consideration the growing interest in the development of environmentally friendly technologies and the recent contributions of our research group in their field. To this end, by using the Ugi-four component protocol we have incorporated lipidic side chains in the architecture of the proyl peptide-peptoid hybrid catalyst. The insertion of functionalities with amphiphilic properties afford to the organocatalyst surfactant properties. Therefore, they have been further evaluated as an organocatalysts in the environmentally friendly enantioselective addition of aldehydes to nitrostyrenes. The Michael adducts were obtained in high yields, diastereoselectivities and excellent enantioselectivities using low catalyst loading under water as solvent without addition of any other additive.

## 1 Introduction

The environmental concerns associated with synthetic organic chemistry have raised rigorous and compelling demands for greener processes. The development of cost-effective and environmentally benign catalytic systems has become one of the main topics of modern chemistry. ${ }^{1,2,3}$ Traditional organic synthesis relies heavily on organic solvents for a multitude of tasks, including the dissolution of components and the facilitation of chemical reactions, since many reactants and reactive species are incompatible or immiscible with water. Since they are used in large quantities compared to the reactant's solvents have been the focus of environmental concerns due to their hazards. ${ }^{4}$ Along with the reduction of the environmental impact of organic synthesis, the use of water as a reaction medium also benefits chemical processes by simplifying operations, allowing moderate reaction conditions and, on occasion, providing unanticipated reactivity and selectivity. ${ }^{5}$

### 1.1 Green Chemistry

According to United State Environmental Protection Agency, the "Green Chemistry": It is the design of chemical products and processes that reduce or eliminate the use or generation of hazardous substances. Green chemistry applies across the life cycle of a chemical product, including its design, manufacture, use, and ultimate disposal. Green chemistry is also known as sustainable chemistry.

[^1]This concept also involves 12 fundamental principles enunciated below: ${ }^{6,7}$

- Waste prevention instead of remediation
- Atom efficiency
- Less hazardous/toxic chemicals
- Safer products by design
- Innocuous solvents and auxiliaries
- Energy efficient by design
- Preferably renewable raw materials
- Shorter syntheses (avoid derivatization)
- Catalytic rather than stoichiometric reagents
- Design products for degradation
- Analytical methodologies for pollution prevention
- Inherently safer processes

Beside to these principles, several metrics have been introduced to measure the degree of greenness and sustainability. Two of the most important are the Atomic Economy (AE) and the environmental factor (E). Professor Barry M. Trost was the first researcher to introduce the term AE, ${ }^{8}$ which is defining as "the ability of a chemical process to incorporate as many as possible of the atoms." and can be calculated by the following equation: ${ }^{9}$, (FIGURE 1).

$$
A E=\frac{M W(\text { product })}{\sum M W(\text { reagent })} \times 100
$$

FIGURE 1. Atom economy is defined as the ratio between the mass of the product obtained and the mass of all the reagents used, expressed in percent.

In this way, chemical transformations that convert most of the starting materials into a single desired product have a high atomic economy and are highly desired transformations in

[^2]terms of sustainability, since they reduce the waste generated, and therefore their environmental impact.

Additionally, Professor Rogers Sheldon has formulated another important metrics, the socalled E Factor. ${ }^{10}$ Almost over twenty years E factor is an environmental measure that expresses the relationship between the amount of product generated and the amount of waste generated in the process ${ }^{11}$, as shown in FIGURE 2.

$$
\text { E Factor }=\frac{k g \text { waste }}{\text { kgproduct }}
$$

FIGURE 2. E Factor equation.
High values of E Factor mean more waste so the ideal value of this measure would be zero. An exception to this factor is that it does not include water as waste, only in some cases the residual salts that are present in it are considered. So, the simple substitution in the use of organic solvents for water could be the switch towards sustainability.

## 1.2 "On Water" or "In Water" Catalysis

In this sense, back to the 1980s, Breslow reported a pioneering work in the acceleration of Diels-Alder reactions performed in water - i.e., $10-15 \mathrm{~min}$ versus $35-40 \mathrm{~min}$ - between cyclopentadiene $\mathbf{1}$ and butanone $\mathbf{2}$ in aqueous emulsion ${ }^{12}$ SCHEME 1.

SCHEME 1. [4+2] cycloaddition accelerated by hydrophobic effect in water.

Theoretical models are mainly focused on an explanation of how the rate of the chemical reactions "on water" or "in water" is accelerated by a water molecule. This has been analyzed

[^3]in comprehensive reviews and articles. ${ }^{13,14}$ Among them, the driving force that explains the rate increase in the water-oil biphasic system was attributed mainly to hydrogen bonding interactions in the interface and hydrophobic effects. ${ }^{15}$

As such concepts, it is debated several types of terms to describe reactions proceeding "in water", "under water", "in aqueous medium", or "on water", "in concentrated organic phases" but none of those adequately represent the effect of water or the difference seem between conditions with water present and solvent-free conditions. About this dilemma, two general terms can be defined "a reaction in water" as one in which the reactant participating in the reaction are dissolved homogeneously in water whereas "a reaction in the presence of water" should be used for a reaction that proceeds in a concentrated organic phase with water being present as a second phase that influences the reaction in the organic phase.

Moreover, in "on water", or "a reaction in the presence of water" catalysis, the transition state occurs at the organic layer of the organic-water interface, this interaction with water is strongly dependent on the properties of each substrate and can be explained by a simple acidcatalysis mechanism facilitated by the strong adsorption of the hydroxide ion by-product at the oil-water interface ${ }^{16}$ (FIGURE 3).

FIGURE 3. "On water" interaction.

### 1.3 Organocatalysis

Organocatalysis, the catalytic application of small organic molecules or also known as catalysis in the absence of metals and enzymes, has become a well-recognized concept and a highly active field of research. In recent years, reactions catalyzed by purely organic molecules have found an increasing field for the synthesis of complex molecules. ${ }^{17,18}$ As a consequence, organocatalysis is unquestionably one of the pillars of asymmetric catalysis together with

[^4]transition metal catalysis and biocatalysis. ${ }^{19}$ Primary chiral amines, thioureas and proline derivatives are the most common organocatalysts used (FIGURE 4).

FIGURE 4. General methods in aminocatalysis
In organic synthesis, we usually think of catalysts as being transition metals, main elements group, and other elements besides C, H, N, and O. Recently, however, there have been significant advances in the organocatalysis field, with the development of new organic systems that have desirable catalytic behaviors. Part of the motivation for such efforts is the air and water instability often associated with metal-based systems, the environmental benefit of avoiding toxic metals, and the ready availability of many enantiomerically pure organic molecules. The well-defined geometry of the system produces very high stereoselectivities. Furthermore, the benefits of inexpensive catalysts and the ability to run the reaction in the open air with wet solvents often more than compensates. Using this approach, a variety of reactions have succumbed to organocatalysis, including Diels-Alder and Friedel-Crafts reactions, direct alkylations of heterocycles such as furan and indole, and a variety of Michael additions. ${ }^{19,20}$

### 1.3.1 Asymmetric Enamine Catalysis

After the pioneering work by List, Lerner, and Barbas employing chiral secondary amines (i.e., proline-type catalysts) to catalyze an intermolecular aldol reactions ${ }^{21}$ and the successive

[^5]expansion of the research interest in organocatalysis. The general concept of enamine catalysis was extensively applied to a wide variety of $\alpha$-functionalization of carbonyl compounds, e.g. aldol reactions, $\alpha$ - aminations, $\alpha$-oxidations and $\alpha$-halogenations, Mannich reactions as well as Michael and hetero Michael reactions (SCHEME 2). ${ }^{22}$

SCHEME 2. Some $\alpha$-functionalization of aldehydes or ketones promoted by proline-type catalysts via enamine. ${ }^{23}$

A rational design is usually an enormous challenge and directly depends on the chosen of asymmetric reaction to pursue. Rarely, the discovery of potential catalysts is successful. The process often involves a separate synthesis of many catalysts and testing their catalytic properties in individual reaction, like test-error. The development of an effective organocatalyst usually needs further optimization process, in which both, the substituents and position of the catalytic functions have been examined towards the reaction of interest.

However, how the pyrrolidine-type catalysts induce stereoselectivity?
Let's explain the enamine activation mechanism, the insights of the stereochemistry induction for the substituents and catalytic function.

It is important to understand the basic principles of enantioselectivity induction to design a new catalyst.

### 1.3.2 Mechanistic aspects

The enamine formation is produced after the condensation between pyrrolidine ring and the correspondent carbonyl group (aldehyde or ketone) as shown in the catalytic cycle (SCHEME 3). The generated enamine has two possible configurational isomers ( $E$ and $Z$ ), ina thermodynamic equilibrium. Unless other general and specific interactions favor the enamine $Z$, the enamine $E$ is energetically most favored and always the formation of this configuration is predominantly. Two rotational isomers (s-trans and $s$-cis) exist in the enamine $E$, whereby steric interactions the most favorable is the $s$-trans-enamine $E$ (SCHEME 3). It is generally accepted that the $s$-trans-enamine is the most stable conformer, where the double bond is situated in the opposite direction to the bulky group located in the 2-position of the pyrrolidine ring.

SCHEME 3. Pyrrolidine-catalyzed activation cycle of enamine.
The $s$-trans conformer has also been considered as the most reactive intermediate until now (vide infra). So far, the role of the pyrrolidine ring is to activate the oxo component increasing the energy of the high occupied molecular orbital (HOMO) of the substrate when the enamine is formed but not in the trajectory of the electrophile in the formation of the new stereogenic CC bond. The trajectory of the electrophile depends on the side group attached to the pyrrolidine ring.

The trajectory of the incoming electrophile has traditionally been proposed to follow either of the two different models (A and B, FIGURE 5) based on the nature of catalysts. Model A shows the induction of stereoselectivity by a hydrogen bond (HB) interaction, and model B shows the approach of the electrophile ruled by steric interaction (SI).

## Model A

Model B
Sterically directing groug

FIGURE 5. Stereocontroller models A and B. Hydrogen Bonding vs. Steric Hindrance
In general, catalysts with a HB directing group (i.e. $-\mathrm{CO}_{2} \mathrm{H},-\mathrm{OH},-\mathrm{CONH}_{2}$, etc... $)^{24,} 25,26$, ${ }^{27,28}$ at the position 2 of the pyrrolidine ring, follows model A (see 4, 5, 6, 7, FIGURE 6). In contrast, bulky substituents in the position 2 of pyrrolidine ring (i.e. $-2 \mathrm{Ph},-2 \mathrm{PhCF}_{3}$, etc...) ${ }^{29,30}$,

[^6]31, 32 where the steric hindrance blocks one face of the enamine, agree with model $B$ of induction of stereoselectivity (see $\mathbf{8}, \mathbf{9}, \mathbf{1 0}$, FIGURE 6). Some pyrrolidine-type catalysts are illustrated again in FIGURE 6 for better understanding; the red color in the structures refers to the respective HB or SI groups.

FIGURE 6. Some pyrrolidine-type catalysts with Hydrogen Bonding or Steric directing groups.

### 1.3.3 Conjugate Michael Addition Reactions of Aldehydes to Nitroolefins

Conjugate addition reactions of carbon nucleophiles to electron deficient double bonds are widely used in organic synthesis in general ${ }^{33}$ and in organocatalytic processes with enamine activation. ${ }^{34,} 35,36$ The Michael reaction is one of the most useful methods for the mild formation of $\mathrm{C}-\mathrm{C}$ bonds that follows an enamine mechanism. It is, amongst other asymmetric reactions, used to test new catalysts based on enamine activation. Nitroalkenes are

[^7]particularly attractive Michael acceptors due to their high electrophilicity ${ }^{37}$ and the synthetic utility of the nitro group. ${ }^{38}$ The conjugate addition of aldehydes to nitroolefins provides $\gamma$ nitroaldehydes that are versatile intermediates for the synthesis of, for example, chiral $\gamma$ butyrolactones, ${ }^{39}$ pyrrolidines, ${ }^{40}$ or $\gamma$-amino acids ${ }^{41}$ (SCHEME 4).

SCHEME 4. Conjugate addition reactions of aldehyde to nitroolefins.
In SCHEME 5 it can be noted that the substituent attached to the pyrrolidine core is important in the direction of the induction in both enantio- and diastereoselectivity of the formed compounds. Four possible transition states (TS) can be drawn for both models (model A and model B, SCHEME 5). These TS show that even with the possibility to form the $s$-cisenamine $E$ (TS III, IV, VII and VIII), the equilibrium is displaced to the formation of the most stable $s$-trans-enamine E (TS I, II, V and VI) of both models, and therefore, the difference in terms of energy between these TS determines the course of stereoselectivity. Model A, also

[^8]known as Houk-List model, ${ }^{42,43}$ (SCHEME 5, TS I-IV) shows an HB between the proton of the carboxylic acid and the nitro group of $\beta$-nitrostyrene. This HB directs the $\beta$-nitrostyrene to the $\boldsymbol{R} \boldsymbol{e}$ face of the enamine by a like approach, thus forming the $S, R$-diastereomer as the major product. However, model B is determined by SI, the bulky group attached to pyrrolidine core produces a steric hindrance capable of approaching the $\boldsymbol{S i}$ face of enamine to $\beta$-nitrostyrene and thus produce the inversed $R, S$-configuration of Michael product (see model B in SCHEME 5). In either case, model A or model B led to the formation of the major diastereomer syn.

Two factors are important for good stereoselection: 1) one face of the enamine must be less accessible; 2) the equilibrium between the enamine rotamers must be well displaced to the one side.

According to SCHEME 5, models A and B having the pyrrolidine-type catalyst with the same configuration produce different stereoisomers. The Re-Re approach is favored for model A and Si -Si for Model B. This makes us conclude that the stereoselection is totally influenced by the linked functional group in the backbone of the catalyst.

[^9]
B) Model B. Steric directing

SCHEME 5. Transition states by HB and SI control in Michael addition: A) HB with S-Proline as catalyst, B) SI with Hayashi's catalyst.

Not only the adopted model of the catalyst and/or backbone of catalysts, but also the intermediates structures formed in the catalytic system can affect the stereoselectivity of the final product. Thereafter, the tridimensional intermediates structure of catalysts and substrates (Transitions States), as well as parasitic intermediates should also be taken in consideration. Blackmond and co-workers ${ }^{44}$ reported a kinetic study of the Michael reaction, where they found a parasitic intermediated which influences the stereoisomers of the final product. In this work, the conjugate addition of $n$-propanal to $\beta$-nitrostyrene, catalyzed by diarylprolinol silyl ether, reveals that the formation of the product (iminium species, SCHEME 6) is the rate-determining step of the reaction, and not the enamine formation as mentioned before. The formation of the cyclobutane intermediate (SCHEME 6), called as `parasitic intermediate' during the catalytic cycle, is very important to keep the high stereoselectivity in the final product. Interestingly, this parasitic intermediate, which should delay the reaction, is important in the stereoselectivity.

[^10]

SCHEME 6. Catalytic system for Michael reaction proposed by Blackmond.
These mechanistic principles help us to design new organocatalysts based in the covalent enamine activation. Although a rational design is usually an enormous challenge, major is to develop new ecofriendly and economic route to access a library of catalysts to test.

### 1.4 Peptides catalysts. A rational design

The invention of peptide synthesis in the $50^{\text {th }}$ stimulated the development of different application areas in which synthetic peptides are now used, including the development of specific antibodies against pathogenic proteins, the study of protein functions, study of enzymesubstrate interactions and catalysis. Every year it is being more evident that combinatorial chemistry can face the synthesis and analysis not only of analogous entities (focused libraries) of previously identified leads but also of truly new catalytic systems based on novel dissimilar chemical functionalities.

Small peptides employed as organocatalysts have molecular weights often comparable to that of typical synthetic catalysts, and they provide the same and, in some cases, better results in asymmetric enamine reactions. ${ }^{45} \mathrm{How}$ can we design a new peptide (or focused library) catalyst?

In the same way, the first step is thinking of the target reaction (i.e., Aldol, Michael, Mannich reaction, etc...), the mechanism and the reaction conditions. Second: selecting the mode of activation (i.e., enamine, iminium...). This step is very dependent of the first step where the peptide in point should carry a secondary or primary amine depending on the asymmetric reaction selected. Third: improving the backbone in the structure of the peptide catalyst considering model A or B explained in SCHEME 5. Some structural motifs of peptides ${ }^{46}$ are represented in FIGURE 8; $\alpha$-helix and $\beta$-turn are the major motifs adopted by small-synthesized peptide catalysts. Fourth: screening peptide catalysts, the catalytic efficiency, stereoselectivity and the scope of catalysts are followed in this step (FIGURE 7).

FIGURE 7. Rational design of a new peptide catalyst.
The secondary structure in peptides is the ordered arrangement or conformation of amino acids unfolded spatially to form the lowest energy conformation. The preferred peptide chain conformation under physiological conditions is dominated by the energetically favored torsion angles, together with

[^11]additional stabilizing factors such as HB and hydrophobic contacts. A hydrogen bonding is formed between the NH group (hydrogen bond donor) and the carbonyl oxygen atom (hydrogen bond acceptor) of peptide bonds. The energy of a single HB is quite low ( $20 \mathrm{kJmol}^{-1}$ ), compared to a covalent bond ( $200-400 \mathrm{kJmol}^{-1}$ ). However, in most secondary structure elements stabilized by HB it is multiple rather than single hydrogen bonds that are formed, and it is these multiple interactions of such a cooperative system that result in considerable stabilization. These interactions cause three different motifs: $\alpha$-helix, $\beta$-sheet, and coil. ${ }^{46, ~ 47}$ Among these secondary structures, $\alpha$-helix and $\beta$-turn motifs are the major structures employed as catalysts.

The $\alpha$-helix comprises a spiral arrangement of the peptide backbone with 3.6 amino acid residues per turn $(\mathrm{n}=3.6)$. It is stabilized by hydrogen bonds directed backwards from a Cterminal NH to an N -terminal $\mathrm{CO}\left(\mathrm{NH}^{\mathrm{i} 4} \rightarrow \mathrm{CO}^{\mathrm{i}}\right.$ ) forming a 13-membered ring (FIGURE 9). Among the types of local structure in proteins, $\alpha$-helix is the most regular and the most predictable from sequence, as well as the most prevalent.

FIGURE 8. Hydrogen bond pattern in $\alpha$-helical peptides and schematic representation.
A turn (loop) is an element of secondary structure in polypeptide or protein where the chain reverses its overall direction. Often, but not necessarily, they are stabilized by an HB between a C-terminal amino group and an N-terminal carboxy group. Turns are classified according to the number of amino acid residues involved as $\gamma$-turns (three amino acids), $\beta$-turn (four amino

[^12]acids), $\alpha$-turn (five amino acids), or $\pi$-turn (six amino acids). $\beta$-turn are very common motifs. A general criterion for the existence of a $\beta$-turn is that the distance of the atoms C (i) and C (i +3 ) is smaller than $7 \AA$. It is stabilized by hydrogen bonds directed backwards from a Cterminal NH to an N -terminal $\mathrm{CO}\left(\mathrm{NH}^{\mathrm{i}+3} \rightarrow \mathrm{CO}^{\mathrm{i}}\right)$. Also, it could be stabilized by certain alkyl residues presented in position $\mathrm{i}+2$ such as $(\alpha, \alpha)$-dialkylglycines such as aminoisobutyric acid (Aib) (FIGURE 9). ${ }^{46}$

FIGURE 9. Hydrogen bond representative of $\beta$-turns. Schematic representation.

### 1.5 Peptides of the Type Pro-Pro-Xaa as Catalysts in Conjugate Addition Reactions between Aldehydes and Nitroolefins

Due to the high degree of rotational freedom even in short peptides, prediction of the conformational properties and thereby the spatial arrangement of functional groups of potential peptide catalysts is a challenge complicating their rational design. Thus, smart combinatorial methods are attractive for the discovery of peptide catalysts. ${ }^{48,49,50}$ The modular nature of linearly linked amino acid building blocks combined with the established synthetic protocols in peptide synthesis (solid phase synthesis), allow for straightforward generation of diverse libraries by the split-and-mix method. Such one-bead-one-compound libraries combined with a cleverly designed screening method and an elegant way of identifying active species allow for the discovery of very potent peptide catalysts. ${ }^{49}$

[^13]Using the concept of catalyst substrate co-immobilisation (FIGURE 10, a) ${ }^{51}$ the two tripeptides H-Pro-D-Ala-D-Asp-NH2 and H-Pro-Pro-Asp-NH2 were identified as excellent catalysts for aldol reactions of acetone with aromatic aldehydes. ${ }^{52}$ The corresponding aldol products were obtained in high enantioselectivities using as little as $1 \mathrm{~mol} \%$ of the peptidic catalyst. Interestingly, in a lowest energy structure obtained by molecular modelling studies the distance between the secondary amine and the carboxylic acid of H-Pro-Pro-Asp- $\mathrm{NH}_{2}$ is approximately $3 \AA$ greater than in proline. Inspired by this fact and hypothesising that these 3 A might provide enough space for two additional atoms (FIGURE 10, b), H-Pro-Pro-Asp-NH2 and closely related peptides Pro-Pro-Xaa, combining the Pro-Pro motif with a C-terminal amino acid containing a carboxylic acid moiety (Xaa), were examined as catalysts for conjugate addition reactions.
a)

b)

FIGURE 10. a.) The principle of catalyst-substrate co-immobilisation: the bead carrying an active catalyst (catalyst 2) becomes labelled with a red dye. b.) The additional distance between the carboxylic acid moiety and the secondary amine of H-Pro-Pro-Asp- $\mathrm{NH}_{2}$ compared to proline. ${ }^{28}$

Indeed, H-Pro-Pro-Asp- $\mathrm{NH}_{2}$ and in particular its diastereoisomer H-D-Pro-Pro-Asp$\mathrm{NH}_{2}$ proved to be very good catalysts for the conjugate addition reaction of various aldehydes to aromatic as well as aliphatic $\beta$-substituted nitroolefins providing the corresponding products in excellent yields, diastereo- and enantioselectivities. ${ }^{53}$ Further studies revealed that the closely related analogue H-D-Pro-Pro-Glu- $\mathrm{NH}_{2}$ is an even better catalyst for conjugate additions

[^14]between aldehydes and nitroolefins ${ }^{54,55}$ Detailed investigations revealed that within the catalyst structure the turn-inducing D-Pro-Pro-motif as well as the C-terminal amide and the carboxylic acid moiety in the side chain are crucial for effective catalysis.

In this sense, other studies done by Wennemers and co-worker ${ }^{56}$ with the analogue H-D-Pro-Pro-Glu- $\mathrm{NH}_{2}$ showed that the trans/cis ratio of the conformers ( $\mathrm{K}_{\text {trans/cis }}$ ) are determinant for the induction of stereoselectivity (SCHEME 7).

SCHEME 7. Trans/cis equilibrium of H-D-Pro-Pro-Glu-NH2 type catalyst.
These studies showed that when the size of the proline ring adjacent to the proline core employed as a catalyst is increased the trans/cis ratio is varied and can be controlled by using a more significant amount of polar aprotic solvents $(\mathrm{CHCl} 3 / \mathrm{i}-\mathrm{PrOH} 9: 1)$ to afford the trans isomer, a marked increase in the trans/cis ratio of their conformers are observed. Tested in a Michael addition of aldehydes to nitroolefins, the best stereoselectivities are obtained for a better $\mathrm{K}_{\text {trans/cis. }}$. In this way, the sequence H -D-Pro-Pip-Glu- $\mathrm{NH}_{2}$ presented the best result.

In counterpart, when the amount of polar protic solvent is increased ( $\mathrm{CHCl} 3 / \mathrm{i}-\mathrm{PrOH} 1: 1$ ), but in this case for adding aldehydes to maleimides, this ratio decreases, and it stops depending on the size of the ring and decreases the stereoselectivity.

[^15]
### 1.6 Water-Compatible Organocatalysis

The development of organocatalytic processes that use water as the reaction medium has attracted widespread attention over the last years ${ }^{57,58,59,60,61}$ because water is the most abundant solvent on earth, non-toxic, non-flammable and easy to handle and thus generally considered as a "green solvent." Since the conjugate addition reaction of carbonyl compounds to nitroolefins is one of the most useful and widely researched organocatalytic transformations, the development and optimization of secondary amine catalysts that allow this reaction to take place in an aqueous medium has received considerable research interest. In this context, several catalysts have been reported that provide the corresponding $\gamma$-nitro carbonyl compounds in

[^16]good yields and stereoselectivities (SCHEME 8). ${ }^{62,63,64, ~ 65, ~ 66, ~ 67, ~ 68, ~ 69, ~ 70 ~ A s ~ t h e ~ w a t e r-s o l u b i l i t y ~}$ of the substrates is generally low, the reaction mixtures are in homogeneous, and the reactions take place in or at the surface of a highly concentrated organic phase. The development of new catalysts that can work in pure water is a challenge, especially for catalyzed asymmetric reactions. The most used approach is the surfactant type design. Many approaches are based on the introduction of lipid chains and others in the use of catalysts in the form of salts to make it soluble in water. Consequently, the secondary amine catalysts that perform best in an aqueous medium are amphiphilic, allowing for their solubility in the organic phase as well as stabilization of an emulsion of the two phases.

[^17]

SCHEME 8. Selected examples of water-compatible organocatalysis.
Our research group has designed a new organocatalyst inspired in the seminal one described independently by Hayashi and Jørgensen. The new catalyst type is modified with lipid side chains and has been used effectively in asymmetric transformations using alternative sustainable solvents. ${ }^{3,} 37,71$

Short peptides have low molecular weight when compare with proteins, but at the same time, consist of the same amino acid building blocks as enzymes. Thus, it is a highly interesting question if and in how far enzymes can be mimicked by their low molecular weight analogues. In this context, Wennemers ${ }^{72}$ reported the first lipopeptide used as an aminocatalyst in additions of Michael using water as a solvent (SCHEME 9).

[^18]

SCHEME 9. Michael addition catalyzed by amphiphilic lipopeptide under aqueous media.
Based on these observations, pyrrolidine-type peptides can be considered as very useful organocatalysts for direct asymmetric catalysis. The major disadvantages of this peptide catalysts remain in the linearity of the synthesis. Peptide synthesis often occurs by coupling the carboxyl group of the incoming amino acid to the N -terminus of the growing peptide chain. The growing peptide chain follows the stepwise method to add amino acids one- at-atime to the growing peptide chain. This produces low yields and atom economy. Peptide coupling requires the activation of the $C$-terminal carboxylic acid of the incoming amino acid using carbodiimides such as dicyclohexylcarbodiimide (DCC) or diisopropylcarbodiimide (DIC). Carbodiimides form such a reactive intermediate that racemization of the amino acid can occur. Therefore, reagents to avoid or reduce racemization are often added, including 1hydroxybenzotriazole (HOBt) and 2-(1H-benzotriazol 1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HBTU). These coupling reagents, resin and additives are expensive and sometimes are unrecovered.

### 1.7 Multicomponent reactions

Multicomponent reactions (MCRs) are convergent processes where three or more compounds react sequentially to form a product that retains most of the atoms of the starting materials. The exact nature of these reactions is difficult to assign given that in the theory of collisions, the simultaneous interaction of three or more molecules results in lower reaction rates. These processes occur through a series of bimolecular reactions, according to a cascade of elementary reactions in equilibrium with a final flow towards an irreversible step that yields the product. Many times, the presence of common substrates allows the occurrence of collateral multicomponent reactions. Conducting a multicomponent reaction in a way that leads to a majority product, will depend on the reaction conditions: solvent, temperature, catalyst, concentration, type of starting materials and functional groups. ${ }^{73}$

[^19]MCRs generally have perfect atom economy and thus represent suitable synthetic tools for addressing the Green Chemistry criterion. Usually, the starting materials of MCRs are readily available, or can easily be prepared.

### 1.7.1 Isocyanide-based multicomponent reactions (I-MCRs)

The chemistry of isocyanides began in 1859 when Lieke obtained allyl-isocyanide by reaction between allyl iodide and silver cyanide. ${ }^{74}$ However, during a whole century, only 12 isocyanides were prepared, whose chemical properties were not investigated in depth due to their unpleasant odor. The isocyanides are characterized by three fundamental chemical properties: i) the acidity of their position $\alpha$, ii) the easy formation of radicals, and iii) the double addition of electrophiles and nucleophiles; its most important chemical property (Scheme 10). ${ }^{75,76,77}$

SCHEME 10. Frontier orbital theory (FOT) of an isocyanide showing its ambiphilic reactivity.
Accordingly, in I-MCRs several chemical bonds are formed with high chemical efficiency, and generating high levels of structural diversity and complexity such as pseudo-peptide (i.e.,

[^20]depsipeptides, ${ }^{78}$ peptoids ${ }^{79,80,81}$ ) and peptidomimetic (e.g., oxa-, ${ }^{82}$ dihydroimida-, ${ }^{83}$ thia-, ${ }^{84}$ and tetrazoles ${ }^{85}$ ) motifs in a diversity-oriented manner without utilization of coupling agents or additives like in peptide chemistry.

### 1.7.2 The Ugi-four component reaction (Ugi-4CR)

The reaction of Ugi is undoubtedly the most used I-MCR, not only in the way of obtaining peptidomimetic structures but also in other very varied ones. Most chemical reactions have their own scope and limitation, whereas the Ugi-4CR can convert almost all combinations of starting materials into their products. Its simplest version is the condensation of an aldehyde or ketone, a primary amine, a carboxylic acid, and an isocyanide to form an N substituted dipeptide. ${ }^{86}$ The use of a prochiral carbonyl compound leads to the formation of mixtures of stereoimomers, because the reaction is not stereoselective ${ }^{87,88,89}$ (SCHEME 11).

[^21]

SCHEME 11. The Ugi four-component reaction (Ugi-4CR).
This reaction consists of an ionic mechanism developed in polar protic solvents (such as methanol). The mechanism of Ugi-4CR is shown in (SCHEME 12). ${ }^{86,90}$ In the first step, the amines and carbonyl compounds (aldehyde or ketone) condensed to the imine. The imine is protonated by the carboxylic acid. Depending on the solvent, the ion can be as salt pair or separately. Then, both ions react with the isocyanide component to form an imidate intermediate. The last step is the Mumm rearrangement, consisting in an intramolecular acylation and subsequent rearrangement forming a $(\mathrm{C}=\mathrm{O})$ double bond and consequently the Ugi product.

SCHEME 12. General mechanism of the Ugi-4CR.
In accord with the ever-increasing demand for 'atom economic' processes and efficient methods to obtain compounds capable inducing good enantioselectivity, I-MCRs are an unexploited and elegant field that deserve to be studied.

[^22]In 2010, Orru and co-workers ${ }^{91}$ published an article with the Ugi type 3CR for the straightforward synthesis of catalyst $\mathbf{2 0}$ (SCHEME 13) resembling the structure and catalytic behavior of Wennemer's catalyst 18.

SCHEME 13. Ugi-type 3CR reaction developed by Orru and co-workers.

Recently, our research group using I-MCR developed the synthesis of a combinatorial library of prolyl peptide-peptoid hybrids and their application as aminocatalysts (Scheme 14). ${ }^{92}$

SCHEME 14. Prolyl peptide-peptoid hybrid catalyst library.
The best catalytic motif was obtained when a (L)-proline, ( $S$ )- $\alpha$-methylbenzylamine, acetone and cyclohexyl isocyanide are combined in the Ugi-4CR. The obtained catalyst 24 showed an exceptional performance in the Michael addition of aldehydes to nitrostryrenes having toluene as a solvent system (SCHEME 15).

[^23]

SCHEME 15. Michael addition of aldehydes to nitrostyrenes.
We have determined the optimized lowest-energy structure of the enamine with $E$ configuration, in toluene as a best solvent for Michael addition. FIGURE 11 shows a significant overlap of the peptidic skeleton to the $\boldsymbol{R e}$-face, which according to Seebach's topological model explains the high enantioselection of the catalyst 24.

FIGURE 11. Lowest-energy structure of the enamine E (s-trans) derived from catalyst $\mathbf{2 1}$.

FIGURE 11 clearly shows that the face ( $\boldsymbol{R e}$-face) of the enamine is totally blocked by the peptidic skeleton (literally as a scorpion). Thus, this clearly justify how this catalyst works in the configuration of enamine E (s-trans) and its influence in the enantioselectivity for Michael adducts.

So, could it be possible to apply I-MCRs, specifically Ugi-4CR, to generate a new class of prolyl peptide-lipopetoid hybrids catalyst library through the introduction of lipidic chains on the same peptide skeleton of the catalyst previously developed by our group, capable to catalyze chemical asymmetric reactions in pure water? Might it be an easy and green way to mix more than one component in a one-pot process to get organocatalysts with surfactant properties?

## 2 Objectives

The application of Ugi-4CR in the field of organocatalysis is a wonderful tool to generate versatility in combinatorial approaches to rapidly, efficiently, and eco-friendly generate peptide derivatives with catalytic potential in asymmetric catalysis. In accord to Green Chemistry principles, the development of new catalyst synthetized with higher atom economy, can be used in pure water is a true challenge and desirable. Therefore, the main target in this work is a synthesis of a combinatorial library of prolyl peptide-lipopeptide hybrids catalysts by Ugi-4CR. Evaluate its amphiphilic and catalytic properties through catalysis via enamine in an addition of aldehydes to nitrostyrenes under water and other environmentally benign solvents. Finally characterize the catalytic system formed by the interaction of the catalyst-water and DFT calculations of the more stable enamine conformation.

## 3 Results and Discussion

### 3.1 Combinatorial multicomponent synthesis of prolyl pseudo-lipopeptides hybrid catalysts

An isocyanide multicomponent reaction (I-MCR) approach based on the Ugi-4CR was carried out for the synthesis and development of a new library of prolyl pseudo-lipopeptides hybrid catalysts (FIGURE 12).

FIGURE 12. Combinatorial multicomponent strategy adopted for the preparation of the prolyl pseudolipopeptide catalysts library.

For the catalyst design, we first have taken into consideration the fact that the $N$ substitution at $\mathrm{R}^{2}$ and the Aib residue derived from the carbonyl component - both beta turn inducers - are responsible for the conformation restrictions (trans/cis equilibrium of the amide bond), therefore shielding one face of the pro-chiral enamine. The influence of the trans/cis conformer ration has been rationalized as one of the main contributors for the high stereoselectivity of this catalyst series. Further, an additional aspect was the high efficiency showed by the Hayashi-Jørgensen type catalyst modified with lipid side chains recently developed and applied by our group. Having these aspects in mind and that three different elements of diversity could precisely be tuned during the multicomponent event (i.e. the amine, the acid and the isocyanide components) we designed a series of prolyl pseudo-lipopeptides hybrid catalysts presented in the FIGURE 12. To this end, (i) acetone was fixed as the carbonyl
component to furnish the Aib moiety in the backbone; (ii) the chiral pyrrolidine core came from $N$-Boc-proline, $N$-Boc-4-hidroxy-proline or from a lipidic derivative of this last one.
(iii) on the other hand, dodecylamine and (S)- $\alpha$-methylbenzylamine were employed as amine components alternatives, and cyclohexyl isocyanide and dodecyl isocyanide were evaluated as isocyanide components. Therefore, it is possible to note that the multicomponent nature of this process enables the direct generation of a series of prolyl pseudo-lipopeptides having the generic sequences $\mathrm{R}^{1}$-Pro- $N-\mathrm{R}^{2}$-Aib- $\mathrm{NHR}^{3}$, being $\mathrm{R}^{1}=\mathrm{H}$, OH, $n-\mathrm{C}_{11} \mathrm{H}_{23} \mathrm{COO} ; \mathrm{R}^{2}=(S)-\alpha-$ MeBn, $n$ - $\mathrm{C}_{12} \mathrm{H}_{25}$, Diphenylmethanamine (Dpm); and $\mathrm{R}^{3}=\mathrm{Cy}, n-\mathrm{C}_{12} \mathrm{H}_{25}$ (TABLE1).

Thus, the Ugi-4CR protocol ${ }^{93}$ was employed for the one-pot assembly of the lipopeptoid skeleton followed purification of the corresponding $N$-Boc protected Ugi adduct by flash chromatography. Under this concept, eight prolyl pseudo-lipopeptides of the type $\mathrm{R}^{1}$-Pro- N - $\mathrm{R}^{2}$ -Aib-NHR ${ }^{3}$ were synthesized in moderate to good yields considering the nature and complexity of this one-pot process (TABLE 1). Finally, the corresponding NH catalysts 24-31 were directly used after the $N$-Boc cleavage.

First, prior to introduce structural changes, the catalyst previously developed by our research group was synthetized employing the already reported protocol. ${ }^{94}$ In this way, the catalyst was obtained in the same yield previously reported ( $77 \%$ yield, TABLE 1, compound 24). Among the three possible elements of diversity, initial attention was given to the amine component by exchanging the ( $S$ )- $\alpha$-methylbenzylamine to dodecylamine (TABLE 1, compound 25). The synthesis of this compound was carried out at room temperature for 24 hours. First, the imine was pre-formed by mixing dodecylamine with acetone in methanol for 2 hours. Subsequently, $N$-Boc-proline and cyclohexyl isocyanide were added to afford the compound 25 with $70 \%$ of yield after additional 22 hours.

The second variation was focused on varying the isocyanide component by exchanging cyclohexyl isocyanide for a lipidic isocyanide. However, dodecyl isocyanide $\mathbf{2 3}$ had to be firstly synthesized from dodecylamine 22 in a one-pot two steps sequence in $71 \%$ of yield (Scheme 16).

[^24]

SCHEME 16. Synthesis of commercially not available lipidic isocyanide 23.

With the isocyanide in hands, the reaction was carried out using $(S)$ - $\alpha$-methylbenzylamine, acetone and $N$-Boc-proline as reaction components under the same conditions previously employed. Thus, compound 26 (TABLE 1) was synthesized in $25 \%$ of yield. The observed low yield shall be rationalized due to two fundamental factors: (a) first, there was no effective formation of the imine at room temperature; (b) second, the lipidic isocyanide and final product were poorly soluble in methanol. Those problems were solved using MW heating for both steps and with the use of approximately $30 \%$ of THF as a co-solvent. This modification in the reaction protocol afforded compound $\mathbf{2 6}$ in $54 \%$ of yield.

${ }^{a}$ All yield is referred of isolated pure N-Boc protected product. ${ }^{b}$ Reaction conducted at room temperature in MeOH for $24 \mathrm{~h} .{ }^{c}$ Reaction conducted under microwave irradiation. ${ }^{d}$ Only imine preforming by microwave irradiation.

With the purpose of introducing two lipid chains at the same time in the same peptidic skeleton as in the Barbas III catalyst ${ }^{67}$ dodecylamine and dodecyl isocyanide were used in an alternative multicomponent reaction using $N$-Boc-proline and acetone under MW irradiation and THF in MeOH as solvent system ( $30 \% \mathrm{v} / \mathrm{v}$ ), archiving compound 27 (TABLE 1) in 57\% of yield. Taking advantage of the main characteristics of surfactants molecules, structures which contain a nonpolar part and a polar part in opposite directions, therefore compound $\mathbf{2 8}$ (TABLE 1) was designed. This approach also had the aim to increase the amphiphilic properties of the catalyst. To achieve the desired catalysts, $N$-Boc-proline was substituted for $N$-Boc-trans-4-hydroxy-
proline as the acid component in a fourth modification. Thus, the combination of $(S)-\alpha-$ methylbenzylamine, acetone, $N$-Boc-trans-4-hydroxy-proline and dodecyl isocyanide afforded compound $\mathbf{2 8}$ in $50 \%$ of yield. This reaction was also carried out using MW heating to preform imine and completed at room temperature to favor the Mumm rearrangement.

The polar pyrrolidine-containing hydroxyl group in the trans position was also used to increase the polarity of the catalyst previously developed by our group. Compound 29 (TABLE 1) could be prepared from acetone, ( $S$ )- $\alpha$-methylbenzylamine, $N$-Boc-trans-4-hydroxy-proline and cyclohexyl isocyanide in $73 \%$ of yield. The presence of a hydroxy group in the pyrrolidine core also opened a new perspective for functionalization. To investigate the effect of the presence of a lipidic portion at this moiety, $N$-Boc-trans-4-hydroxy- proline was acylated ${ }^{95}$ with lauryl chloride and then used as an acid component, affording compound $\mathbf{3 0}$ (TABLE 1) in $48 \%$ of yield. In this case, the imine was also pre-formed under MW heating and the reaction could be completed at room temperature.

Finally, one last consideration in the design of the catalytic motifs was carried out. Tothis end a structural change was made based on compound 28, that in theory presents the best surfactant type design. In this approach, the chiral amine ( $S$ )- $\alpha$-methylbenzylamine incorporated in compound $\mathbf{2 8}$ was replaced by the more hindered 2.2-diphenylglycine methyl ester. Interestingly, after preparing the methyl ester and use as an amine component in the Ugi reaction - employing the imine preformation under MW and allowing the completion of reaction at room temperature - the final product undergoes decarboxylation, affording compound 31 (TABLE 1) in $55 \%$ of yield. This decomposition probably occurs in the preformation of the imine in methanol at $70{ }^{\circ} \mathrm{C}$, through a nucleophilic attack of methanol to the methyl ester, which gives rise to dimethylcarbonate and diphenylmethanamine (SCHEME 17).

[^25]

SCHEME 17. Decarboxylation mechanism of the 2.2-diphenylglycine methyl ester hydrochloride during the preformation of imine in methanol.

To summarize, eight aminocatalysts have been synthesized, among then, seven are new in the literature. A peptoid (compound 29) and six lipopeptoids presenting a wide structural diversity and catalytic motifs.

### 3.2 Prolyl pseudo-lipopeptide hybrid catalysts: Evaluation in the asymmetric Michael reaction under aqueous media

To evaluate the catalytic behavior of the prolyl pseudo-lipopeptides in the conjugate addition reactions of aldehydes to nitroolefins, we chose to use $n$-butanal and ( $E$ )-(2-nitrovinyl) benzene as model reaction (TABLE 2). As standard conditions a mixture of the $\beta$-nitrostyrene and 2 equivalents of the aldehyde, were vigorously stirred in pure water ( 0.5 M concentration of the nitroolefin), in the presence of $10 \mathrm{~mol} \%$ of each catalyst, at room temperature for 24 hours. Prior to beginning the evaluation of the new catalysts synthesized by this new methodology, the catalyst previously synthesized in our group (compound 24) was evaluated (Entry 1, TABLE 2). As expected, this catalyst showed good results, both enantioselectivity ( $95 \%$ e.e.) and diastereoselectivity ( $98: 2$ d.r.), however a low yield (34\%) was observed. The very low yield shall be related to the low solubility of the organocatalyst in water and the lack of surfactant proprieties. With this result in hands, we started to evaluate the new lipopeptoids based organocatalysts. Compound $\mathbf{2 5}$ showed significant improvements in terms of
performance ( $75 \%$ of yield), but lower d.r. (76:24) and e.e. (85\%) were observed (Entry 2, TABLE 2). This preliminary result was very encouraging since our proposed methodology seemed to work well in completely aqueous media. Then, compound $\mathbf{2 6}$ was furtherevaluated, the lipid chain in the opposite direction of the pyrrolidine nucleus showed improvements in terms of yield (88\%), d.r. (89:11) and e.e. (92\%) (Entry 3, TABLE 2). We expected an excellent result for compound 27 since the design was centered on a structure similar to Barbas III catalyst. However, this catalyst did not work as expected, since good performance ( $71 \%$ of yield) but low selectivity ( $87 \%$ e.e. and $87: 13$ d.r.) were observed (Entry 4, TABLE 2). At this point of the catalyst screening, the results obtained were good mainly in terms of yields, but not yet satisfactory in terms of stereoselectivity.

TABLE 2. Asymmetric Michael reaction of $n$-butanal and $\beta$-nitrostyrene. Screening of different prolyl pseudo-lipopeptide catalysts. ${ }^{a}$

${ }^{c}$ Determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of the reaction mixture. ${ }^{d}$ Determined by chiral-stationary phase HPLC or UPC ${ }^{2}$ analysis.

An excellent performance was also expected for compound 28, since the presence of a free hydroxyl group in pyrrolidine ring would likely provide a better solubility. To our delight, us
expectative became true, since a high yield accompanied by an excellent e.e. (99\%) was observe when the reaction was performed using this catalyst (Entry 5, TABLE 2). At that moment, it became clear that the introduction of an additional chiral center was essential to the improvement of the enantioselectivity. To confirm this, we have observed that the introduction of this same chiral center into the catalyst previous developed in our group afforded better results in performance ( $43 \%$ of yield) and enantioselectivities ( $99 \%$ of e.e.), although a significant decrease in diastereoselectivity (d.r.: 70:30) was observed (Entry 6, TABLE 2). The maintenance of the enantioselectivity and slightly higher d.r. was observed when the $O$ substituted $N$-Boc-trans- $4-\mathrm{C}_{11} \mathrm{H}_{23} \mathrm{COO}$-proline had its catalytic behavior evaluated. However, a very poor yield (23\%) was obtained (Entry 7, TABLE 2). In this case, despite the presence of a lipid chain, it is placed on the polar side of the pyrrolidine nucleus, which leads to erosion in terms of amphiphilicity. Additionally, this compound is extremely hydrophobic, so its behavior in water is limited. The reaction performed using catalyst (compound 31, Entry 8, TABLE 2), afforded the product in $84 \%$ of yield, $79: 21$ d.r. and $89 \%$ e.e. The decrease in selectivity could be attribute to the replacement of a chiral ( $S$ )- $\alpha$-methylbenzyl in the side chain of the lipopeptoid backbone by an achiral, but bulky diphenylmethane. These results showed that the presence of a chiral center in this portion of the catalyst is also determinant for the stereoselection.

### 3.3 Optimization of the catalytic system

From the results presented in TABLE 2, catalyst 28 was chosen for the next set of optimization experiments, since it was considered to have the best combination yield/enantioselectivity. As show in TABLE 3, we next evaluated catalyst loading and the nature of the environmentally benign solvent under room temperature. Most of these reactions were performed in triplicate to evaluate if the results obtained were reproducible (Entry 1, 2; 4-6 and 7-9, TABLE 3). Firstly, we turned our attention to study the amount of catalyst in the Michael reaction. By lowering the catalyst loading to $5 \mathrm{~mol} \%$, the desired product 34 was obtained in higher yield and excellent enantioselectivity, however, a moderate diastereoisomeric ratio could be observed (Entry 3, TABLE 3). Further decreasing the catalyst loading to $2.5 \mathrm{~mol} \%$, yields above $90 \%$ are obtained, again with a concomitant improvement in the diastereomeric ratio and the maintenance of enantiomeric excesses (99\%) (Entry 4-6, TABLE 3). The use of $1 \mathrm{~mol} \%$ of the catalyst leads to an erosion on chemical yields (Entry 79, TABLE 3). The main differences in the obtained results in the catalyst loading study shall be
associated to the stability of the self-assembled water-oil catalytic system that is formed in dependence on the quantities of catalyst. The use of $10 \mathrm{~mol} \%$ of catalyst forms a self-assembled water-oil system that is very stable and emulsified, therefore hydrophobic effects are responsible for the slight decrease in yield and diastereoselectivity. While the use of $1 \mathrm{~mol} \%$ of catalyst forms an unstable water-oil system, and although the results in terms of d.r. and e.e. were high, chemical yields are very poor, since the system formed does not allow the solubility of the starting materials (so the intermediates) or the desired product. Thus, $2.5 \mathrm{~mol} \%$ of catalyst is sufficient to maintain good yields and enantioselectivities in pure water.

TABLE 3. Asymmetric Michael reaction of $n$-butanal and $\beta$-nitrostyrene catalyzed by 28. Optimization of the system. ${ }^{a}$

| Entry | Catalyst (mol\%) | Solvent | Yield (\%) $^{b}$ | ${\text { d.r. }(\text { syn:anti })^{c}}^{\text {e.e. }(\%)^{d}}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 10 | $\mathrm{H}_{2} \mathrm{O}$ | 76 | $87: 13$ | 98 |
| 2 | 10 | $\mathrm{H}_{2} \mathrm{O}$ | 87 | $76: 24$ | 98 |
| 3 | 5 | $\mathrm{H}_{2} \mathrm{O}$ | 90 | $90: 10$ | 99 |
| 4 | 2.5 | $\mathrm{H}_{2} \mathrm{O}$ | 95 | $93: 7$ | 99 |
| 5 | 2.5 | $\mathrm{H}_{2} \mathrm{O}$ | 96 | $93: 7$ | 99 |
| 6 | 2.5 | $\mathrm{H}_{2} \mathrm{O}$ | $99(96)$ | $93: 7$ | 99 |
| 7 | 1 | $\mathrm{H}_{2} \mathrm{O}$ | 46 | $98: 2$ | 99 |
| 8 | 1 | $\mathrm{H}_{2} \mathrm{O}$ | 45 | $98: 2$ | 99 |
| 9 | 1 | $\mathrm{H}_{2} \mathrm{O}$ | 65 | $98: 2$ | 99 |
| 10 | 2.5 | Ethanol | 26 | $85: 15$ | 98 |

| 12 | 2.5 | PEG-300 | 54 | $82: 18$ | 98 |

${ }^{a}$ Reactions using 2 equivalents of $n$-butanal and 0.2 mmol of $\beta$-nitrostyrene in 0.4 mL of solvent. ${ }^{b}$ Yield determined by ${ }^{1} \mathrm{H}$-NMR analysis with 1,2,3-trimethoxybenzene as standard (isolated product).
${ }^{c}$ Determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of the reaction mixture. ${ }^{d}$ Determined by chiral-stationary phase UPC ${ }^{2}$ analysis.

Furthermore, we decided to evaluate other green and sustainable solvents, employing 2.5 mol\% of catalyst loading. Three systems were examined (ethanol, brine and PEG-300) as alternative solvents of water. When the reaction was performed using ethanol and PEG-300 (Entry 10 and 12, TABLE 3 ) the desired products are obtained in low yields and good stereoselectivities. The observed yield could be rationalized mainly since these solvents completely dissolve the reagents. Therefore, there is no formation of a water-oil biphasic system. On the other hand, a good result was obtained when brine was evaluated (Entry 11, TABLE 3), showing that our catalytic system depends fundamentally on the formation of a biphasic water-oil system and not of an emulsified or micellar system.

### 3.4 Scope and Limitations

Encouraged by these results and using the best reaction conditions for our catalytic system, we next explored the scope and limitations of this enamine-type catalytic reaction with a variety of aldehydes and several substituted nitrostyrenes in the para position (TABLE 4).

TABLE 4. Scope of catalyst 28 in the asymmetric Michael reaction between different aldehydes and $\beta$-nitrostyrenes. ${ }^{a}$

34
${ }^{b}$ yield: $99(96) \%$ ${ }^{c}$ d.r: : 97:3 ${ }^{d}$ e.e.: $99 \%$

38
${ }^{b}$ yield: $95(91) \%$
${ }^{c}$ d.r: : 92:8
${ }^{d}$ e.e.: 99\%

35
${ }^{b}$ yield: $91 \%$
${ }^{c}$ d.r: : 92:8
${ }^{d}$ e.e.: $99 \%$

39
${ }^{b}$ yield: $96(94) \%$
${ }^{c}$ d.r: : 92:8
${ }^{d}$ e.e.: $98 \%$

36
${ }^{b}$ yield: 79\%
${ }^{c}$ d.r: : 99:1
${ }^{d}$ e.e.: $99 \%$

40
${ }^{b}$ yield: $87(84) \%$
${ }^{c}$ d.r. : 93:7
${ }^{d}$ e.e.: $96 \%$

37
${ }^{b}$ yield: 91(89)\%
${ }^{c}$ d.r. : 92:8
${ }^{d}$ e.e.: $98 \%$

41
${ }^{b}$ yield: $89(80) \%$
${ }^{c}$ d.r.: 89:11
${ }^{d}$ e.e.: $97 \%$
${ }^{a}$ All reactions were conducted using 2 equivalents of aldehyde and 0.2 mmol of $\beta$-nitrostyrene in 0.4 mL of water. ${ }^{b}$ Yield determined by ${ }^{1} \mathrm{H}$-NMR analysis with $1,2,3$-trimethoxybenzene as standard and (isolated product). ${ }^{c}$ Determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of reaction mixture. Determined by chiralstationary phase UPC ${ }^{2}$ analysis.

All reactions were conducted in water at room temperature for 24 h in the presence of 2.5 mol\% catalyst 28. In each case, smooth reactions occurred to generate Michael adducts in high yields ( $80-96 \%$ ), diastereoselectivities up to 99:1 and excellent enantioselectivities (from 96to $99 \%$ e.e.). By increasing the carbon side chain of the aldehyde, the desired product 35 was delivered in the good yield and excellent estereoselectivity. Moreover, performing the reaction in the presence of an aldehyde bearing a bulkier substituent in the $\beta$-position (i.e.
isovaleraldehyde) afforded lower yield (79\%), but 99:1 dr. and 99\% ee have been observed (product 36, TABLE 4). As depicted, $\beta$-nitrostyrenes bearing $\beta$-aryl substituents with moderate electron withdrawing effect by electronegativity and electron donor due to mesomeric effect (i.e, $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$ ) had a similar behaviour in water. In all these cases, high yields and excellent estereoselectivies were observed (products 37-39, TABLE 4). Besides, the reaction also showed to be non-affected by the presence of strong $\beta$-aryl electron-rich or electron-withdrawing substituents. Intriguingly, a slight decrease in terms of yield, as well as on the stereoselectivity were observed for the formation of produtcs 40 and 41.

These results demonstrate that the new prolyl-lipopeptoid hybrid catalyst 28 can be faced as a good catalyst for conjugate addition reactions between a different substituted aromatic nitroolefins and aldehydes. It is also important to emphasize that no additive was needed to assist the catalytic activity, which implies in an even more sustainable process.

### 3.5 Conformational Study

FIGURE 13. Conformational structure of the optimized enamine. In red, the oxygen atoms are represented. In blue are the atoms of nitrogen, in gray the carbon atoms and in white the hydrogen atoms.

The enamine type structure was optimized in a Gaussian 09 program, which afforded the conformation shown in FIGURE 15. ${ }^{96}$ Although not so precisely, this simple schematic

[^26]representation of the enamine supports the explanation of the observed enantiomeric discrimination. The enamine configuration is $E$ (s-trans), which is likely the more stable conformation, where the long alkyl chain is completely blocking one of the faces of the enamine, that is, the $R e$-face. However, since it is a simple approximation proposed, a more accurate DFT calculations still necessary.

## 4 Conclusions

In conclusion, a new catalyst library based on the prolyl peptide-lipopeptoid hybrid has synthesized by Ugi-4CR. Thus, variation of three elements of diversity at the Ugi-derived $N$ substituted peptide led to eight prolyl pseudo-lipopeptides catalysts of the type of Pro-N-R ${ }^{1}$ -Xaa- $\mathrm{NHR}^{3}$ in moderate to good yields ( $48-77 \%$ ). This showed a remarkable improvement in terms of chemical performance, maintaining high stereoselectivity compared to the catalyst previously developed by our research group under these reaction conditions in aqueous media. A low charge of the catalyst $\mathbf{2 8}$ ( $2.5 \mathrm{~mol} \%$ ) was necessary to afford the products with excellent yield, diastereoselectivity and enantioselectivity without any further additive.

## 5 Perspectives

$\rightarrow$ We intend to carry out a conformational study of the catalysts, as well as to increase the number of examples of the scope.
$\rightarrow$ The use of $N$-Boc-trans-4-hydroxy-proline- as acid component could provide alternatives for the further modifications on the hydroxyl group in this type of catalyst e.g. lipid, pegylated, or support in a solid support that can be polystyrene and polyethylene glycol resins or in silica to be able to recycle it.
$\rightarrow$ Due to the results presented for the prolyl pseudo-lipopeptide catalyst 28 in Michael reaction under aqueous media we consider that new asymmetric reactions should be evaluated in a sustainable way, especially remote asymmetric funcionalizations (i.e. trienamine).

## 6 Experimental Section

### 6.1 General Aspects

Materials and reagents were of the highest commercially available grade purchased from Sigma-Aldrich, Oakwood Chemicals, and Strem Chemicals and used without further purification. Flash chromatography was performed using silica gel 60 , particle size $40-63 \mu \mathrm{~m}$ and analytical thin layer chromatography (TLC) was performed using silica gel aluminum sheets. Compounds were visualized on TLC by UV, $\mathrm{KMnO}_{4}, \mathrm{I}_{2}, \mathrm{H}_{3}\left[\mathrm{P}^{\left.\left(\mathrm{Mo}_{3} \mathrm{O}_{10}\right)_{4}\right] \cdot \mathrm{xH}_{2} \mathrm{O} \text { (PMA) }}\right.$ and Vanillin solutions. Solvents for extractions and for column chromatography were previously distilled. Chemical yields were given after chromatographical purification. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at 400 MHz for ${ }^{1} \mathrm{H}$ and 100 MHz for ${ }^{13} \mathrm{C}$, respectively. Chemical shifts ( $\delta$ ) are reported in parts per million relatives to the residual solvent signals and coupling constants $(J)$ are reported in hertz. High resolution ESI mass spectra were obtained from a Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometer, an RF-only hexapole ion guide and an external electrospray ion source. HPLC analysis were carried out on an analytical HPLC with a diode array detector SPD-M20A from Shimadzu using Chiralpak column (OD-H) ( $250 \mathrm{~mm} \times 4.6 \mathrm{~mm}$ ) from Daicel Chemical Ind. LTD. UPLC analysis were carrie out on Acquity UPC ${ }^{2}$ system from Waters with a 2998 photodiode array (PDA) and Xevo TQD triple cuadrupolo mass spectrometry detectors using Trefoil columns (CEL2 and AMY1) ( $2.1 \mathrm{~mm} \times 50 \mathrm{~mm}$ ) from Waters. Optical rotations were measured on a Perkin Elmer Polarimeter 341.

### 6.2 General procedures

### 6.2.1 Synthesis of commercially not available lipidic isocyanide.

General procedure for the synthesis of isocyanide 23: In a 50 mL bottom flask, commercially dodecylamine ( $2.00 \mathrm{~g}, 11 \mathrm{mmol}$ ) was dissolved in ethyl formate ( 20 mL ). The resulting solution was refluxed for 24 h at $60^{\circ} \mathrm{C}$ in a silicon bath and the quantitative formation of formamide was checked by TLC ( $n$-Hexane/EtOAc 1: 1 ). The reaction was concentrated by reduced pressure; the crude product was dissolved in triethylamine ( 30 mL ) and cooled down to $-70{ }^{\circ} \mathrm{C}$. Then $\mathrm{POCl}_{3} 3 \mathrm{~mL}$ ( 33 mmol ) was added drop by drop during 15 min under argon atmosphere. The reaction allowed stirring at room temperature for 48 h and after this period the resulting mixture was decanted. The solid obtained was washed with $n$-Hexane ( $2 \times 25 \mathrm{~mL}$ ), decanted and the fractions of sobrenadant were united. The solvent was removed by reduced pressure and the resulting very viscous oil is directly purified by column chromatography
(Petroleum ether) to obtain pure dodecyl isocyanide as a light-yellow oil ( $1.50 \mathrm{~g}, 71 \%$ ). $\boldsymbol{R} \mathbf{f}=$ 0.83 ( $n$-Hexane/EtOAc 10: 1).

## Spectroscopic data of dodecyl isocyanide 23:

${ }^{1} \mathbf{H}$ NMR $\left(400 \mathrm{MHz}, \mathbf{C D C l}_{3}\right) \delta=3.41-3.35(\mathrm{~m}, 2 \mathrm{H}), 1.72-1.63(\mathrm{~m}, 2 \mathrm{H}), 1.48-1.38(\mathrm{~m}$, $2 \mathrm{H}), 1.32-1.24(\mathrm{~m}, 16 \mathrm{H}), 0.88(\mathrm{t}, J=6.9 \mathrm{~Hz}, 1 \mathrm{H})$.
${ }^{13} \mathbf{C}$ NMR ( $\mathbf{1 0 1} \mathbf{~ M H z}, \mathbf{C D C l}_{3}$ ) $\delta=155.43,60.40,41.57,31.91,29.60,29.51,29.37,29.33$, 29.11, 28.71, 26.32, 22.68, 14.12.

### 6.2.2 Synthesis of prolyl pseudo-lipopeptides by Ugi-4CR

General procedure for the synthesis of compound 25: A solution containing acetone (3 equiv.) and amine ( 1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in methanol was stirred at room temperature for 2 hours to preform the imine. After the addition of carboxylic acid (1.2 equiv.) and isocyanide ( 1 equiv.), the resulting mixture was allowed to stir at room temperature for 24 h . Finally, the solvent was removed under reduced pressure and the residue was purified by column chromatography.

## Spectroscopic data of compound 25:

Dodecylamine ( $56 \mathrm{mg}, 0.3 \mathrm{mmol}$ ), acetone ( $44 \mu \mathrm{~L}, 0.6 \mathrm{mmol}$ ), $N$-Bocproline ( $52 \mathrm{mg}, 0.24 \mathrm{mmol}$ ), cyclohexyl isocyanide ( $25 \mu \mathrm{~L}, 0.2 \mathrm{mmol}$ ) and anhydrous sodium sulfate ( $85 \mathrm{mg}, 0.6 \mathrm{mmol}$ ) were reacted in $\mathrm{MeOH}(200 \mu \mathrm{~L})$ according to the procedure described above. The resulting Boc protected compound was subjected to flash column chromatography purification (EtOAc/n-Hexane 7:3) affording the lipopeptoid hybrid $2(77 \mathrm{mg}, 70 \%)$ as a colorless oil.
$\boldsymbol{R}_{\mathbf{f}}=0.60(\mathrm{EtOAc} / n-$ Hexanes 7:3).
$[\alpha]{ }^{20}=$ n.d.
${ }^{1} \mathbf{H}$ NMR $\left(400 \mathrm{MHz}, \mathbf{C D C l}_{3}\right) \delta=5.76(\mathrm{~d}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}), 4.48(\mathrm{dd}, J=7.6,3.5 \mathrm{~Hz}, 1 \mathrm{H}), 3.74$
$-3.49(\mathrm{~m}, 2 \mathrm{H}), 3.47-3.31(\mathrm{~m}, 2 \mathrm{H}), 3.31-3.15(\mathrm{~m}, 2 \mathrm{H}), 2.26-2.02(\mathrm{~m}, 2 \mathrm{H}), 1.98-1.76(\mathrm{~m}$,
$7 \mathrm{H}), 1.73-1.54(\mathrm{~m}, 4 \mathrm{H}), 1.46-1.41(\mathrm{~m}, 13 \mathrm{H}), 1.35-1.18(\mathrm{~m}, 20 \mathrm{H}), 1.16-0.98(\mathrm{~m}, 3 \mathrm{H}), 0.87$ (t, $J=6.8 \mathrm{~Hz}, 3 \mathrm{H}$ ).
${ }^{13} \mathbf{C}$ NMR ( $\mathbf{1 0 1} \mathbf{~ M H z}, \mathbf{C D C l}_{3}$ ) $\delta=174.09,173.29,154.53,79.41,62.82,56.95,48.61,47.17$, $44.61,33.04,32.74,32.51,31.90,31.25,30.34,29.60,29.32,29.13,28.62,27.01,25.55,25.48$, 25.21, 24.97, 24.30, 23.82, 23.07, 22.68, 14.11.

General procedure for the synthesis of compound 24,26 and 27: A solution containing acetone ( 3 equiv.) and amine ( 1.5 equiv.) and anhydrous sodium sulfate ( 3 equiv.) in $\mathrm{MeOH} / \mathrm{THF}(2: 1 \mathrm{v} / \mathrm{v})$ was stirred under microwave irradiation at $70{ }^{\circ} \mathrm{C}$ during 10 min to preform imine. After the carboxylic acid ( 1.2 equiv.) and isocyanide ( 1 equiv.) were added, the resulting mixture was stirred under microwave irradiation (at $70{ }^{\circ} \mathrm{C}$ ) during 30 min . Finally, the solvent was removed under reduced pressure and the residue was purified by column chromatography. Note: Only THF was used for the synthesis of compounds $\mathbf{3}$ and 4.

## Spectroscopic data of compound 24:

(S)- $\alpha$-methylbenzylamine ( $39 \mu \mathrm{~L}, 0.3 \mathrm{mmol}$ ), acetone ( $44 \mu \mathrm{~L}, 0.6$ mmol ), $N$-Boc-proline ( $52 \mathrm{mg}, 0.24 \mathrm{mmol}$ ), cyclohexyl isocyanide ( 25 $\mu \mathrm{L}, 0.2 \mathrm{mmol}$ ) and anhydrous sodium sulfate ( $85 \mathrm{mg}, 0.6 \mathrm{mmol}$ ) were reacted in $\mathrm{MeOH}(200 \mu \mathrm{~L})$ according to the procedure described above. The resulting Boc protected compound was subjected to flash column chromatography purification ( $n$ Hexane/EtOAc 7:3) affording the peptoid hybrid $\mathbf{1}(75 \mathrm{mg}, 77 \%)$ as a colorless oil.
$\boldsymbol{R}_{\mathbf{f}}=0.30$ ( $n$-Hexane/EtOAc 7:3).

### 6.2.3 Boc deprotection of prolyl pseudo-lipopeptides using TFA

General procedure: The $N$-Boc pure product resulting for the Ugi-4CR was cooled and dissolved in 1 mL of a mixture of TFA/ $\mathrm{CH}_{2} \mathrm{Cl}_{2} 9: 1 \mathrm{v} / \mathrm{v}$ at $0^{\circ} \mathrm{C}$. The reaction mixture was allowed to stir for 30 min and then concentrated to reduced pressure (TFA was removed completely by repetitive addition and evaporation of further $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ). The crude was dissolved in 10 mL of EtOAc and washed with satured $\mathrm{NaHCO}_{3}(3 \times 10 \mathrm{ml}$ ), brine ( 10 ml ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and filtered evaporated under reduced pressure afforded to desired product.

### 6.2.4 General procedure for asymmetric $\mathbf{1 , 4}$-addition of aldehydes to nitrostyrenes.

General procedure: A vial, was charged with the prolyl pseudo-lipopeptide $\mathbf{2 8}$ (X mol\%), the nitroolefin ( $0.2 \mathrm{mmol}, 1.0$ equiv) and 0.4 mL of water. The mixture was homogenized in an ultrasound bath, treated with the aldehyde ( $0.40 \mathrm{mmol}, 2.0$ equiv) and was stirred for 24 h . After this period, the resulting reaction mixture was extracted with EtOAc, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated under reduced pressure. The yield was determined by ${ }^{1} \mathrm{H}$ NMR analysis of resulting crude product with 1.2.3-trimethoxybenzene ( $0.2 \mathrm{mmol}, 1.0$ equiv) as standard patron. The crude product was purified by flash column chromatography on silica gel using $n$-hexane/EtOAc as eluent only for the compounds that require it. The distereoisomeric ratio was determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of reaction mixture. Enantiomeric excess (e.e.) was determined by chiral HPLC or UPC ${ }^{2}$ analysis through comparison with the authentic racemic material.

Spectroscopic data of compound 34: 2-ethyl-4-nitro-3-phenylbutanal

Prepared by reaction of $n$-butanal with trans- $\beta$-nitrostyrene according to the procedure described above. The compound was purified by flash column chromatography ( $n$-Hexane/EtOAc 9:1). The enantiomeric excess was determined by chiral-stationary phase UPC ${ }^{2}$. Trefoil CEL2, CO2/EtOH 100$0 \%$ to $95-5 \%$ in 10 min at $3 \mathrm{ml} / \mathrm{min}$ at $25^{\circ} \mathrm{C}$. UV detection at $210 \mathrm{~nm}: \mathrm{R}_{\mathrm{t}}:($ syn, major) $=4.13$ $\min ,(\operatorname{syn}, \operatorname{minor})=3.93 \mathrm{~min}$.

# Synthesis of $N$-alkylated lipopeptides and their application as organocatalysts in asymmetric Michael addition in aqueous environments $\dagger$ 

José A. C. Delgado, (1) ${ }^{\text {a }}$ Fidel E. M. Vicente, ${ }^{\text {ab }}$ Alexander F. de la Torre, ${ }^{\text {c }}$ Vitor A. Fernandes, (D) Arlene G. Corrêa (D) ${ }^{a}$ and Márcio W. Paixão (D) *a

#### Abstract

A library of $N$-alkylated lipopeptide organocatalysts were synthesized through an isocyanide-based multicomponent reaction. Various structural motifs were tunably introduced on the catalyst backbone with the aim of incorporating amphiphilic features. Consequently, they have further been evaluated in the 1,4-addition of aldehydes to trans- $\beta$-nitrostyrene having water as the sole solvent. Under sustainable reaction conditions, Michael adducts were obtained in excellent yields, diastereoselectivities, and enantioselectivities using low catalyst loadings and without additives.

## Introduction

The construction of carbon-carbon bonds is one of the leading chemical transformations in organic synthesis, especially in a stereoselective fashion. ${ }^{1}$ Amongst a plethora of strategies already developed, asymmetric aminocatalysis, since its conception, has posed as one of the most important tools for forging C-C and C-X bonds. ${ }^{2}$ Consequently, many prolinebased organocatalysts have been successfully developed and further applied to a variety of synthetic transformations in the presence of traditional organic solvents. ${ }^{3}$ However, environmental concerns associated with synthetic organic chemistry have posed stringent and compelling demands for greener processes. Over the past few years, the replacement of organic solvents for an environmentally benign reaction medium has been pursued by the synthetic community in a quest for the improvement of green metrics. ${ }^{4}$

In this regard, amphiphilic or water-compatible organic molecules which successfully catalyzed asymmetric chemical transformations "in-water", "on-water" or in the presence of a small amount of water have been widely used as an excellent environmentally benign alternative. ${ }^{5}$ These molecules hold

[^27]both hydrophilic and hydrophobic portions in their chemical architecture, which allow them to act at the water-oil interface by decreasing superficial tension. ${ }^{6}$ Due to its intrinsic characteristics, amphiphilic molecules have widespread applications, mainly as surfactants, ${ }^{7}$ and more recently in catalytic transformations in aqueous environments. ${ }^{8}$

Moreover, when an amphiphilic catalyst is employed under aqueous conditions, two systems with different physicalchemical features - micelles or self-assembly emulsions - are expected to be formed, and therefore the catalysis could be performed either inside the micelle ${ }^{9}$ or at the water-oil interface. ${ }^{10}$

In this way, there are numerous reports in the literature that have explored either the catalytic properties of micelles or the amphiphilic properties of appropriate organocatalysts in challenging asymmetric transformations. ${ }^{11}$

Wennemers and co-workers took advantage of the hydrophilic nature of peptides developed through an efficient lipopeptide-based organocatalyst by introducing on the C-terminus a long alkyl chain in the known catalytic structural motif (H-(D)Pro-Pro-Glu-NH2). ${ }^{12}$ This lipopeptide displayed both high activity and stereocontrol upon the Michael addition of aldehydes to nitrostyrene under aqueous conditions through emulsion formation (Scheme 1A). Moreover, Alves and co-workers designed a new lipopeptide-catalyzed stereoselective aldol reaction in an aqueous microstructured environment (micellar catalysis). ${ }^{13}$

Likewise, we have also been involved in the design of new catalytic structural motifs by exploiting the synthetic ability of isocyanide-based multicomponent reactions (I-MCRs) to generate structural diversity (Scheme 1B). ${ }^{14}$ Therefore, we planned to introduce a long alkyl chain onto the chemical architecture

Scheme 1 (A) Amphiphilic lipopeptide organocatalyst having a H-(D)Pro-Pro-Glu- $\mathrm{NHC}_{12} \mathrm{H}_{25}$ sequence. (B) Prolyl peptide-peptoid hybrid catalyst assembly by Ugi-4CR having a Pro-N((S)-MeBn)-Aib-NHCy structural motif. of the organocatalyst previously developed by our group to generate an amphiphilic system (Scheme 1C).

## Results and discussion

Herein, we describe a new amphiphilic organocatalyst which is capable of performing a stereoselective carbon-carbon bond forming reaction in an aqueous environment. We started our investigation by synthesizing a library of $N$-alkylated lipopeptides through a widely employed isocyanide-based multicomponent approach, the Ugi-4CR (Ugi-4-component reaction). Under this environmentally benign reaction protocol, prolyl pseudo-lipopeptides were obtained in moderate to excellent yields ( $35-81 \%$ ), having the generic sequence of $\mathrm{R}^{1}$-Pro- N -alkyl-Aib-NHR ${ }^{2}$ (Scheme 2A). With the library of $N$-alkylated lipopeptide organocatalysts in hand, we turned to the evaluation of their catalytic performance in the Michael reaction, which is one of the most employed methods for both carboncarbon and carbon-heteroatom bond formation. For the initial catalyst screening, butyraldehyde and trans- $\beta$-nitrostyrene were chosen as model substrates (Scheme 2B). These reactions were carried out using a catalyst loading of $10 \mathrm{~mol} \%$, and water as the solvent at room temperature. In all cases, the

Scheme 2 (A) Structures and yields of $N$-alkylated lipopeptides synthesized in this work. (B) Screening of organocatalysts 3a-3k upon the addition of butyraldehyde to trans- $\beta$-nitrostyrene. All reactions were carried out using 2 equivalents of butanal and 0.2 mmol of $\beta$-nitrostyrene in 0.4 mL of solvent. The yield was determined by ${ }^{1} \mathrm{H}$ NMR spectroscopic analysis of the crude reaction mixture with 1,2 , 3-trimethoxybenzene as the internal standard. The syn/anti ratio was determined by ${ }^{1} \mathrm{H}$ NMR and the enantiomeric excess was determined via chiral-stationary phase UPC ${ }^{2}$ analysis.
stereoselectivity is influenced by the proline-core and conformational rigidity of the catalyst, thereby leading to the formation of the Michael adduct predominantly with the syn relationship and $(R, S)$-absolute configuration. ${ }^{15}$

Moreover, many of the evaluated organocatalysts - specifically 3a-h - delivered the desired product 4a with moderate to excellent diastereo- and enantioselectivities. These results are in agreement with a previous observation by our group, ${ }^{14,16}$ where the beta-turn structural motif $-N((S)$-MeBn)-Aib- is required to achieve high levels of stereoinduction (compare $3 \mathbf{a}-\mathbf{h} v$. $3 \mathbf{i}-\mathbf{k}$ ). Besides, no considerable difference in terms of enantioselectivity was observed among the organocatalysts of this series.

Notwithstanding the relative water-solubility of these N alkylated lipopeptides and due to the nonsoluble nature of
organic compounds, the reaction mixtures were a heterogeneous slurry or a biphasic water-oil system of the substrates in the aqueous medium. In this sense, the introduction of a long alkyl chain - of twelve carbon atoms - at the $R^{2}$ position improves the reaction performance, and hence the catalysts bearing the sequence $\mathrm{R}^{1}$ - $\operatorname{Pro}-N((S)-\mathrm{MeBn})$-Aib- $\mathrm{NHC}_{12} \mathrm{H}_{25}$ (i.e., $\mathbf{3 b}, \mathbf{3 e}-\mathbf{f}$, and $\mathbf{3 j}-\mathbf{k}$ ) render the products in a higher chemical yield. On the other hand, the organocatalyst 3a, previously developed by our group, afforded 4 a in a moderate chemical yield ( $57 \%$ ). Based on these observations, we assume that the hydrophobic effect is the main factor that causes the improvement in terms of efficiency of the Michael reaction in an aqueous environment. Additionally, the insertion of a lipidic side chain at the $R^{1}$ position ${ }^{17}$ triggered an erosion in terms of yield ( $\mathbf{3} \mathbf{h}$ ). The hydroxyl group remains as a hydrophilic part or head whereas the long alkyl chain acts as a hydrophobic part or tail, reinforcing its amphiphilic features and allowing it to act as a tenside. Besides, neither the incorporation of the hydrophobic chain nor the achiral bulky ( $N$ - $\alpha$-diphenylmethane) as an $N$-alkyl substituent into the catalyst backbone gave better results for the asymmetric organic transformation than previously discussed catalysts (i.e., $\mathbf{3 i} \mathbf{- j}$ and $\mathbf{3 k}$ ). The fine-tuning of the $R^{1}$ and $R^{2}$ substituents incorporating the three-dimensional beta-turn structural motif led to the organocatalyst trans-OH-Pro- $N((S)-\mathrm{MeBn})$-Aib- $\mathrm{NHC}_{12} \mathrm{H}_{25}(3 \mathbf{e})$, which afforded the desired Michael adduct in 88\% yield, 76:14 d.r. and 99\% e.e.

Once a suitable catalyst was identified, we continued the optimization study by evaluating the catalyst loading of $3 \mathbf{e}$, and the influence of other environmentally friendly solvents (Table 1).

As shown in Table 1, by decreasing the catalyst loading to $5 \mathrm{~mol} \%$, the chemical yield was slightly improved and the enantioselectivity of the Michael adduct $\mathbf{4 a}$ remained at the same level - albeit, a great improvement was observed in the diastereoselectivity ratio (Table 1, entry 1 ). To our delight, with a catalyst loading of $2.5 \mathrm{~mol} \%$, compound 4 a was obtained in quantitative yield and with excellent levels of stereoselectivity (Table 1, entry 2). Notwithstanding, upon decreasing the catalyst loading to $1 \mathrm{~mol} \%$, the reaction underwent an erosion in terms of chemical efficiency (Table 1, entry 3), although nonsubstantial changes in diastereoselectivity and enantioselectivity could be observed. Then, we turned our attention to evaluate the

Table 1 Optimization of the system. All reactions were carried out using 2 equivalents of butanal and 0.2 mmol of trans- $\beta$-nitrostyrene in 0.4 mL of solvent for 24 h . The yield was determined by ${ }^{1} \mathrm{H}$ NMR spectroscopic analysis of the crude reaction mixture with 1,2,3-trimethoxybenzene as the internal standard (yield of the isolated product). The syn/anti ratio was determined by ${ }^{1} \mathrm{H}$ NMR and the enantiomeric excess was determined by chiral-stationary phase UPC ${ }^{2}$ analysis

| Entry | Deviation from initial conditions | Yield <br> (\%) | d.r. <br> syn:anti | e.e. (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Using $5 \mathrm{~mol} \%$ of catalyst loading | 90 | 90:10 | 99 |
| 2 | Using $2.5 \mathrm{~mol} \%$ of catalyst loading | 99 (96) | 93:7 | 99 |
| 3 | Using $1 \mathrm{~mol} \%$ of catalyst loading | 52 | 98:2 | 99 |
| 4 | Brine instead water | 84 | 95:5 | 99 |
| 5 | Ethanol instead water | 26 | 85:15 | 99 |
| 6 | PEG-300 instead water | 54 | 82:18 | 99 |

influence of other greener solvents on the catalytic activity. When brine is used instead of water, the reaction undergoes a slight change in the chemical efficiency (Table 1, entry 4). Moreover, both ethanol and polyethylene glycol (PEG-300) delivered the Michael adduct in low chemical yield, however, with moderate diastereoselectivity and high enantioselectivity (Table 1, entry 5 and 6). A visual schematic representation of the optimized condition in different stages is depicted in Fig. 1 showing the emulsion formation upon the addition of all substrates to the amphiphilic organocatalyst $3 \mathbf{e}$ in water.

With these notably improved reaction conditions in hand, we explored the scope of the Michael addition between different aldehydes and trans- $\beta$-nitrostyrene mediated by the organocatalyst 3 e in an aqueous environment (Scheme 3).

Gratifyingly, the extension of this sustainable transformation to hexanal, under the previously established optimized reaction conditions, resulted in the formation of product $\mathbf{4 b}$ in 91\% yield, with $99 \%$ e.e. and $92: 8$ d.r. When isovaleraldehyde was used as the donor, the reaction proceeded efficiently, affording the corresponding product $\mathbf{4 c}$ in $79 \%$ yield, with high levels of stereoselectivities (d.r.: 99:1, e.e.: 99\%). Additionally, $(R)-(+)$-Citronellal was also compatible with the reaction, which led to the desired Michael adduct $\mathbf{4 d}$ with moderate yield, good diastereoselectivity and high enantioselectivity.

Moreover, a representative selection of trans- $\beta$-nitrostyrenes was evaluated to establish the generality of this asymmetric catalytic system. Of particular note, nitrostyrene bearing distinct substituents, either electron-withdrawing groups (i.e., F, $\mathrm{Cl}, \mathrm{Br}, \mathrm{NO}_{2}$ and $\mathrm{CF}_{3}$ ) (4e-i, 4m) or electron-donating groups (i.e., OMe, Me and $t$-Bu) ( $\mathbf{4} \mathbf{j}-\mathbf{l}, \mathbf{4 n}$ ) gave the desired Michael adducts in moderate to excellent yields as well as diastereoselectivities and maintained enantioselectivity ranges of $96-99 \%$. Interestingly, modification of the aromatic ring to introduce heterocycles such as furan was also well tolerated (compound 4o, 83\% yield, 99\% e.e. and 82:18 d.r.). Moreover, alteration to alkyl-substituted nitroolefins also afforded the corresponding products in good yield and excellent stereoselectivity ( $\mathbf{4} \mathbf{p}$ and $\mathbf{4 q}$ ).

Performing the reaction on a 2 mmol scale under a prolonged reaction time of 72 hours afforded $\mathbf{4 a}$ in a similar yield and enantioselectivity, albeit with a drop in the diastereoisomeric

Fig. 1 (A) catalyst 3 e in water; (B) mixture of butyraldehyde and trans- $\beta$ nitrostyrene in water; (C) mixture of butyraldehyde, trans- $\beta$-nitrostyrene and catalyst 3 e in water; and (D) mixture of butyraldehyde, trans- $\beta$ nitrostyrene and catalyst 3 e in water after being stirred for 24 h .

4c yield:79\%(n.d.)
d.r.:99:1 e.e.: $99 \%$

Scheme 3 Scope of reaction with catalyst 3 e. All reactions were conducted using 2 equivalents of the aldehyde and 0.2 mmol of $\beta$-nitrostyrene in 0.4 mL of water. The yield was determined by ${ }^{1} \mathrm{H}$ NMR spectroscopic analysis of the crude reaction mixture with $1,2,3$-trimethoxybenzene as the internal standard (yield of the isolated product). The diastereoisomeric ratio was determined by ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture and the enantiomeric excess was determined by chiral-stationary phase UPC ${ }^{2}$ analysis. Note: The diastereoisomeric ratio for isolated products changes upon purification and the values are reported in the ESI, $\dagger$ Section 17.
ratio (see the ESI $\dagger$ for further details, $90 \%$ yield, $72: 28$ d.r. and $99 \%$ e.e.). To our delight, catalyst recycling was easily achieved after filtration over a pad of silica flash using ethyl acetate as the mobile phase for eluting the crude product with the organocatalyst being trapped on the silica. Afterwards, the organocatalyst could be recovered by passing methanol through the silica and evaporating the solvent. Moreover, under the optimized reaction conditions, the recovered organocatalyst 3 e was successfully subjected to four cycles delivering the desired product $4 \mathbf{a}$ with a stable tendency for reproducibility over each cycle (see the ESI $\dagger$ for further information).

## Conclusions

In summary, we have developed an amphiphilic $N$-alkylated lipopeptide (3e) which presented extraordinary catalytic activity in the asymmetric Michael addition of aldehydes to trans- $\beta$ nitrostyrene in water - neither organic solvent nor additional additives were found to be necessary in this sustainable reaction protocol. This new catalytic system is appropriate for functionalization of an array of trans- $\beta$-nitroolefins, including aromatic and aliphatic, in good to excellent yields and stereoselectivities under low catalyst loadings. Furthermore, the
reaction could be easily scaled-up and the catalyst could be recycled, delivering the Michael adduct with similar results in both cases. Hence, these remarkable advantages make this catalytic system suitable for future pharmaceutical developments and opens new perspectives in stereoselective organic synthesis in water.

## Experimental

## Materials and methods

All solvents were dried and distilled before use using standard procedures and the reagents were of the highest commercially available grade purchased from Sigma-Aldrich, Oakwood Chemicals, and Strem Chemicals and used as received or purified according to the procedures outlined in Purification of Common Laboratory Chemicals. ${ }^{18}$ Glassware used was dried in an oven or flame dried under a vacuum and cooled under an inert atmosphere. Column flash chromatography was performed using silica gel 60 (230-400 mesh), and thin-layer chromatography (TLC) analysis was performed using silica gel aluminum sheets. Compounds were visualized on TLC by UV-light, $\mathrm{KMnO}_{4}, \mathrm{I}_{2}, \mathrm{H}_{3}\left[\mathrm{P}^{2}\left(\mathrm{Mo}_{3} \mathrm{O}_{10}\right)_{4}\right] \times \mathrm{H}_{2} \mathrm{O}$ (PMA) and Vanillin. Yields refer to chromatographically and spectroscopically pure compounds unless otherwise noted. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at 400 and 100 MHz , respectively. Chemical shifts ( $\delta$ ) are reported in parts per million relative to the residual solvent signals, ${ }^{19}$ and coupling constants (J) are reported in hertz. The following abbreviations indicate the multiplicity of each signal: (s), singlet; (bs), broad singlet; (d), doublet; (t), triplet; (q), quartet; (p), pentet; (m), multiplet; (dd), doublet of doublets; (dt), doublet of triplets; (dq), doublet of quartet; (dp), doublet of pentet; (td), triplet of doublets; (ddt), doublet of doublet of triplets; (dtd), doublet of triplet of doublets; (ddd), doublet of doublet of doublets; (dddd), doublet of doublet of doublet of doublets; (heptd), heptet of doublets. High-resolution ESI mass spectra were obtained using a Waters Acquity UPLC H-class liquid chromatograph coupled with a Waters Xevo G2-XS QToF mass spectrometer with an electrospray interface (ESI). HPLC analysis was carried out on an analytical HPLC using a diode array detector SPD-M20A from Shimadzu using a Chiralpak column OD-H ( $250 \mathrm{~mm} \times$ 4.6 mm ) from Daicel Chemical Ind. LTD. UPLC analysis was carried out on an Acquity UPC ${ }^{2}$ system from Waters using a 2998 photodiode array (PDA) and Xevo TQD triple quadrupole mass spectrometer as detectors using Trefoil columns CEL2 and AMY1 ( $2.1 \mathrm{~mm} \times 50 \mathrm{~mm}$ ) from Waters. Optical rotations were measured on a PerkinElmer polarimeter.

## General procedures for the synthesis of prolyl pseudolipopeptides by Ugi-4CR:

General procedure A. A solution containing acetone (3 equiv.), amine ( 1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in MeOH was stirred at room temperature for 2 hours. After the addition of carboxylic acid (1.2 equiv.) and isocyanide
(1 equiv.), the resulting mixture was allowed to stir at room temperature for 24 h . Finally, the solvent was removed under reduced pressure and the residue was subjected to a deprotection procedure and purified using column chromatography.

General procedure B. A solution containing acetone (3 equiv.) and amine ( 1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in $\mathrm{MeOH} / \mathrm{THF}(2: 1 \mathrm{v} / \mathrm{v}$ ) was stirred under microwave irradiation at $70{ }^{\circ} \mathrm{C}$ for 10 min . After the carboxylic acid ( 1.2 equiv.) and isocyanide ( 1 equiv.) were added, the resulting mixture was stirred under microwave irradiation (at $70{ }^{\circ} \mathrm{C}$ ) for 30 min . Finally, the solvent was removed under reduced pressure and the residue was subjected to a deprotection procedure and purified using column chromatography.

General procedure C. A solution containing acetone (3 equiv.), amine ( 1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in $\mathrm{MeOH} / \mathrm{THF}(2: 1 \mathrm{v} / \mathrm{v})$ was stirred under microwave irradiation at ( $70{ }^{\circ} \mathrm{C}$ ) during 10 min to preform the imine. After carboxylic acid (1.2 equiv.) and isocyanide (1 equiv.) were added, the resulting mixture was allowed to stir at room temperature for $24-48 \mathrm{~h}$. Finally, the solvent was removed under reduced pressure and the residue was subjected to the deprotection procedure and purified using column chromatography.

## $N$-Boc deprotection procedure of prolyl pseudo-lipopeptides:

The crude $N$-Boc product of the Ugi-4CR was dissolved in 1 mL of a mixture of TFA/DCM $9: 1 \mathrm{v} / \mathrm{v}$ at $0^{\circ} \mathrm{C}$. The reaction mixture was allowed to stir for 30 min and then concentrated under reduced pressure (TFA was entirely removed by repetitive addition and evaporation of further DCM). The crude product was dissolved in 10 mL of DCM and neutralized over anhydrous $\mathrm{K}_{2} \mathrm{CO}_{3}$, filtered and evaporated under reduced pressure afford the crude product.

## General procedure for asymmetric 1,4-addition of aldehydes to nitrostyrenes

A vial was charged with the prolyl pseudo-lipopeptide hybrid catalyst $3 \mathbf{e}$ ( $2.5 \mathrm{~mol} \%$ ), the nitrostyrene ( $0.2 \mathrm{mmol}, 1.0$ equiv.) and 0.4 mL of water. The mixture was homogenized in an ultrasound bath, the aldehyde ( $0.40 \mathrm{mmol}, 2.0$ equiv.) was added and this mixture was stirred for 24 h . After this period, the resulting reaction mixture was extracted with EtOAc, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated under reduced pressure. The crude product was purified by flash column chromatography on silica gel using n-hexane/EtOAc as the eluent. The diastereoisomeric ratio was determined by ${ }^{1} \mathrm{H}$ NMR analysis of the crude reaction mixture. Enantiomeric excess (e.e.) was determined by chiral HPLC or UPC ${ }^{2}$ analysis through comparison with the authentic racemic material. Assignment of the stereoisomers was performed by comparison with literature data. ${ }^{3 f}$

## 1. General Information

All solvents were dried and distilled before use by standard procedures and reagents were of the highest commercially available grade purchased from SigmaAldrich, Oakwood Chemicals, and Strem Chemicals and used as received or purified according to the procedures outlined in Purification of Common Laboratory Chemicals. ${ }^{1}$ Glassware used was dried in oven or flame dried under vacuum and cooled under an inert atmosphere. Column flash chromatography was performed using silica gel 60 (230-400 mesh), and analytical thin-layer chromatography (TLC) was performed using silica gel aluminum sheets. Compounds were visualized on TLC by UV-light, $\mathrm{KMnO}_{4}, \mathrm{I}_{2}, \mathrm{H}_{3}\left[\mathrm{P}_{\left.\left(\mathrm{Mo}_{3} \mathrm{O}_{10}\right)_{4}\right] \times \mathrm{H}_{2} \mathrm{O} \text { (PMA) and Vanillin. Yields refer to }}\right.$ chromatographically and spectroscopically pure compounds unless otherwise noted. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at 400 and 100 MHz , respectively. Chemical shifts ( $\delta$ ) are reported in parts per million relative to the residual solvent signals, ${ }^{2}$ and coupling constants $(J)$ are reported in hertz. the following abbreviations indicate the multiplicity of each signal: (s), singlet; (bs), broad singlet; (d), doublet; ( t ), triplet; (q), quartet; (p), pentet; (m), multiplet; (dd), doublet of doublets; (dt), doublet of triplets; (dq), doublet of quartet; (dp), doublet of pentet; (td), triplet of doublets; (ddt), doublet of doublet of triplets; (dtd), doublet of triplet of doublets; (ddd), doublet of doublet of doublets; (dddd), doublet of doublet of doublet of doublets; (heptd), heptet of doublets. High-resolution ESI mass spectra were obtained from a Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometer, an RF-only hexapole ion guide and an external electrospray ion source. HPLC analysis were carried out on an analytical HPLC with a diode array detector SPD-M20A from Shimadzu using Chiralpak column OD-H ( $250 \mathrm{~mm} \times 4.6 \mathrm{~mm}$ ) from Daicel Chemical Ind. LTD. UPLC analysis was carried out on Acquity UPC² system from Waters with 2998 photodiode array (PDA) and Xevo TQD triple quadrupole mass spectrometry as detectors using Trefoil columns CEL2 and AMY1 ( $2.1 \mathrm{~mm} \times 50 \mathrm{~mm}$ ) from Waters. Optical rotations were measured on a Perkin Elmer Polarimeter.

## 2. Synthesis of lipidic isocyanides

General procedure A

In a 50 mL bottom flask, aliphatic amine $1 \mathrm{a}-\mathrm{c}$ ( 11 mmol ) was dissolved in HCOOEt ( 20 mL ). The resulting solution was refluxed at $60^{\circ} \mathrm{C}$ for 24 h in a silicone bath and the quantitative formation of formamide was verified by TLC (hexanes/EtOAc 1:1). The reaction was concentrated to dryness, the crude mixture was dissolved in $\mathrm{NEt}_{3}(30 \mathrm{~mL})$ and cooled to $-70^{\circ} \mathrm{C}$. Then $\mathrm{POCl}_{3}(3 \mathrm{~mL}, 33 \mathrm{mmol}, 3$ equiv.) was added dropwise during 15 min under argon atmosphere. The reaction mixture was stirred at room temperature for 48 h . The resulting mixture was decanted; the solvent removed by reduced pressure and the resulting very viscous oil was directly purified by column chromatography (hexanes, until 10\% of EtOAc). The fractions containing the product were combined and evaporated under reduced pressure to give the corresponding isocyanides 2a-c.

## 3. Characterization data of compounds 2a-c

1-isocyanododecane (2a) ${ }^{3}$ :The title compound was synthesized according to the general procedure A in $71 \%(1.50 \mathrm{~g})$ isolated yield as a light yellow oil. $\boldsymbol{R}_{\boldsymbol{f}}=0.83$ (hexanes/EtOAc 10:1). NMR ${ }^{1} \mathrm{H}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 3.41-3.35(\mathrm{~m}, 2 \mathrm{H}), 1.72-1.63(\mathrm{~m}, 2 \mathrm{H}), 1.48-1.38$ (m, $2 \mathrm{H}), 1.32-1.24(\mathrm{~m}, 16 \mathrm{H}), 0.88(\mathrm{t}, \mathrm{J}=6.9 \mathrm{~Hz}, 3 \mathrm{H}) . \mathrm{NMR}^{13} \mathrm{C}\left(100 \mathrm{MHz}, \mathrm{CDCI}_{3}\right) \delta 155.6$, 60.5, 41.7, 32.0, 29.7, 29.6, 29.5, 29.5, 29.2, 28.8, 26.5, 22.8, 14.3.

1-isocyanohexane (2b) ${ }^{4}$ : The title compound was synthesized according to the general procedure A in $65 \%(795 \mathrm{mg})$ isolated yield as a light yellow oil. $\boldsymbol{R}_{\boldsymbol{f}}=0.90$ (hexanes/EtOAc 10:1). NMR ${ }^{1} \mathbf{H}\left(\mathbf{4 0 0} \mathbf{~ M H z}, \mathbf{C D C l}_{3}\right)$ ठ 3.38 (td, J = 6.7, $2.1 \mathrm{~Hz}, 2 \mathrm{H}$ ), 1.73 - 1.62 (m, 2H), 1.44 (p, J = $7.2 \mathrm{~Hz}, 2 \mathrm{H}), 1.37$ -

4. General procedures for the synthesis of prolyl pseudo-lipopeptides by Ugi-4CR

General Procedure B: A solution containing acetone (3 equiv.), amine (1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in MeOH was stirred at room temperature for 2 hours. After the addition of carboxylic acid (1.2 equiv.) and isocyanide (1 equiv.), the resulting mixture was allowed to stir at room temperature for 24 h . Finally, the solvent was removed under reduced pressure and the residue was subjected to deprotection procedure E and purified by column chromatography.

General Procedure C: A solution containing acetone (3 equiv.) and amine (1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in MeOH/THF ( $2: 1 \mathrm{v} / \mathrm{v}$ ) was stirred under microwave irradiation at $70{ }^{\circ} \mathrm{C}$ during 10 min . After the carboxylic acid ( 1.2 equiv.) and isocyanide ( 1 equiv.) were added, the resulting mixture was stirred under microwave irradiation (at $70^{\circ} \mathrm{C}$ ) for 30 min . Finally, the solvent was removed under reduced pressure and the residue was subjected to deprotection procedure $E$ and purified by column chromatography.

General Procedure D: A solution containing acetone (3 equiv.), amine (1.5 equiv.) and anhydrous sodium sulfate (3 equiv.) in $\mathrm{MeOH} / \mathrm{THF}(2: 1 \mathrm{v} / \mathrm{v}$ ) was stirred under microwave irradiation at $\left(70^{\circ} \mathrm{C}\right)$ during 10 min to preform the imine. After carboxylic acid ( 1.2 equiv.) and isocyanide ( 1 equiv.) were added, the resulting mixture was allowed to stir at room temperature for 24-48 h. Finally, the solvent was removed under
reduced pressure and the residue was subjected to deprotection procedure E and purified by column chromatography.

## 5. N-Boc deprotection of prolyl pseudo-lipopeptides

General procedure E: The crude $N$-Boc product of the Ugi-4CR was dissolved in 1 mL of a mixture of TFA/DCM $9: 1 \mathrm{v} / \mathrm{v}$ at $0^{\circ} \mathrm{C}$. The reaction mixture was allowed to stir for 30 min and then concentrated to reduced pressure (TFA was entirely removed by repetitive addition and evaporation of further DCM). The crude was dissolved in 10 mL of DCM and neutralized over anhydrous $\mathrm{K}_{2} \mathrm{CO}_{3}$, filtered and evaporated under reduced pressure afforded to the crude product.

TABLE 1. Synthesis of prolyl pseudo-lipopeptides by Ugi-4CR.

## 7. General procedure for asymmetric 1,4 -addition of butanal to trans- $\beta$ nitrostyrene: Catalyst Screening

General procedure F: A vial was charged with the prolyl pseudo-lipopeptides hybrid catalyst 3a-k (10 mol\%), trans- $\beta$-nitrostyrene ${ }^{7}$ ( $0.2 \mathrm{mmol}, 1.0$ equiv.) and 0.4 mL of water. The mixture was homogenized in an ultrasound bath, butanal $(0.40 \mathrm{mmol}, 2.0$ equiv.) was added and this mixture was stirred for 24 h . After this period, the resulting reaction mixture was extracted with EtOAc, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated under reduced pressure. The yield was determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude product with 1.2.3-trimethoxybenzene ( $0.2 \mathrm{mmol}, 1.0$ equiv.) as internal standard. The crude product was purified by flash column chromatography on silica gel using hexanes/EtOAc ( $9: 1 \mathrm{v} / \mathrm{v}$ ) as eluent. The diastereoisomeric ratio was
determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of the reaction mixture. Enantiomeric excess (e.e.) was determined by chiral HPLC or UPC² analysis through comparison with the authentic racemic material.

TABLE 2. Catalysts Screening.

${ }^{a}$ All reactions were conducted using 2 equivalents of the aldehyde and 0.2 mmol of $\beta$-nitrostyrene in 0.4 mL of water; ${ }^{b}$ Yield determined by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis with 1,2,3-trimethoxybenzene as internal patron and (isolated product); ${ }^{c}$ Determined by ${ }^{1} \mathrm{H}$ NMR of crude of the reaction mixture;
${ }^{d}$ Determined by chiral-stationary phase HPLC or UPC ${ }^{2}$ analysis.

## 10. Scale-up

A vial was charged with the prolyl pseudo-lipopeptide hybrid catalyst $3 \mathrm{e}(2.5 \mathrm{~mol} \%$, 24 mg ), the nitrostyrene ${ }^{7}(2 \mathrm{mmol}, 298 \mathrm{mg}, 1.0$ equiv, $)$ and 4 mL of water. The mixture was homogenized in an ultrasound bath, the butanal ( $4 \mathrm{mmol}, 361 \mu \mathrm{~L}, 2.0$ equiv) was added and this mixture was stirred for 72 h . After this period, the
resulting reaction mixture was extracted with EtOAc, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated under reduced pressure. The crude product was purified by flash column chromatography on silica gel using (hexanes/EtOAc 9:1) to afford 4a in $90 \%(400.4 \mathrm{mg})$ as a colorless oil. The diastereoisomeric ratio was determined by ${ }^{1} \mathrm{H}$ NMR analysis of crude of the reaction mixture. Enantiomeric excess (e.e.) was determined by chiral UPC ${ }^{2}$ analysis through comparison with the authentic racemic material.

a) Catalyst 3 e in water; b) After the addition of nitrostyrene and butanal; c) After 72 h of reaction.

## 11. Catalyst recycle

A vial was charged with the prolyl pseudo-lipopeptide hybrid catalyst $\mathbf{3 e}$ ( $10 \mathrm{~mol} \%$ ), the nitrostyrene ${ }^{7}$ ( $0.2 \mathrm{mmol}, 1.0$ equiv), and 0.4 mL of water. The mixture was homogenized in an ultrasound bath, the aldehyde ( $0.40 \mathrm{mmol}, 2.0$ equiv) was added and this mixture was stirred for 24 h . After this period, the resulting reaction mixture was extracted with EtOAc, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concentrated under reduced pressure. The crude product was filtered by a small amount of silica flash using ethyl acetate to afford $\mathbf{4 a}$ in as follows in Table 2, entry 5. After that, the catalyst remains in the silica, and it is recovered by passing 50 ml of methanol through the silica. Then, the solvent was removed by reduced pressure on rotovapory and transferred to the 5 ml vial, and dried under a high vacuum for 2 h . After this period, the nitrostyrene ${ }^{7}$ ( $0.2 \mathrm{mmol}, 1.0$ equiv) and 0.4 mL of water were added into the vial containing the catalyst. The mixture was homogenized in an ultrasound bath, the aldehyde ( $0.40 \mathrm{mmol}, 2.0$ equiv) was added and this mixture was stirred for 24 h . The procedure was carried out over four times and the results
are depicted in Figure 2. The yield was determined by ${ }^{1} \mathrm{H}$ NMR analysis of the crude product with 1.2.3-trimethoxybenzene ( $0.2 \mathrm{mmol}, 1.0$ equiv.) as an internal standard. The diastereoisomeric ratio was determined by 1H NMR analysis of crude of the reaction mixture. Enantiomeric excess (e.e.) was determined by chiral UPC ${ }^{2}$ analysis through comparison with the authentic racemic material.
